no significant difference in the proportion of attachment (p = 0.9262) of attachment between adult males (54%) and adult females (53%). However, the same test showed a highly significant difference (p = 2.766e-13) in algal occurrence between adult turtles (combined sexes, 34%) and immature (<14.5 cm PL, 15%). Edgren et al. (1953) also found few juveniles with algae. No *Basicladia* were found on White Oak hatchlings or immatures in September or October. Most hatching and emergence occur at the site during this period. The small turtles probably inhabit shallower, warmer waters at that time than do adults and either come into less contact with algal spores or do not give the algae enough time to form distinct shell colonies before hibernation.

The relationship between algae and Snapping Turtles seems to be one of mutualism, with both parties gaining benefit from the others' presence (Edgren et al. 1953; Neill and Allen 1954). It is thought that turtles acquire a certain amount of camouflage through enhanced growth of algal colonies on their shell and skin, which conceals them from would-be predators, while also providing concealment from prey, allowing the turtles to use a sit-and-wait feeding strategy (Neill and Allen 1954). Adult *C. serpentina* spend much time submerged and sometimes obtain prey through ambush (Ernst and Lovich 2009). However, Edgren et al. (1953) thought camouflage of little importance in view of the general absence of natural predators upon adult turtles (especially *C. serpentina* at White Oak; Ernst, pers. obs.). Algae, in return, gain a point of attachment from which colonies can grow, a moving base providing better dissemination of spores as turtles migrate from one waterbody to another, and, possibly, protection from some small algae grazers. Unfortunately, neither of these hypotheses has been tested. A disadvantage of an algae-turtle relationship is the possibility that the algae may penetrate beneath the epidermal scutes of the shell and cause necrosis. Hunt (1958) reported a case of indirect necrosis of algal origin in the European turtle, *Emys orbicularis*.

Leeches.—The only species of leech found at White Oak was *Placobdella parasitica*, a commonly reported ectoparasite of *C. serpentina*. The occurrence of only one species of *Placobdella* at White Oak is unusual (see above references). The incidence of infestation of Snapping Turtles with leeches was 33% (92 of 280 captures). Other White Oak turtles experienced the following rates of *Placobdella* infestation: *Chrysemys picta*, 11%; *Clemmys guttata*, 12%; *Glyptemys insculpta*, 39%; *G. muhlenbergii*, 4%; and *S. odoratus*, 37% (Ernst 1971a, 1976, 1986, 2001, 2011).

Although *C. serpentina* were captured from March into October, leeches were only found attached from April through September (Table 2). Most infestation occurred during the period May through August (see below), when the incidence was more than 30% of the turtles collected during those individual months. Table 2 shows an increasing occurrence beginning in April (23%) and continuing through August, decreasing in September (12%). Colder ATs and WTs may possibly have contributed to the decrease in incidence at both ends of the turtle's annual cycle, with no leeches remaining attached during the winter months (as has been observed elsewhere; see above citations). In addition, the leech's normal behavior may contribute to their decline in the fall; it may be that more leeches that fed on the turtles became satiated, dropped off to digest their meals, and were then prevented from attaching by colder temperatures and the turtle's burying into the soft bottom. As snapping turtles hibernate most often totally buried in the soft bottom of some waterbody or buried beneath the soil on land (Ernst and Lovich 2009), a lack of oxygen at the hibernation site (Ultsch and Reese 2008) may also play a role in ridding the turtle of aerobic leeches.

As environmental temperatures increase with the advance of spring, the turtle emerges and comes once again in contact with leeches. Although relatively rare, *Chelydra* do bask out of water on occasion (Ernst and Lovich 2009). During aerial basking, attached leeches are sometimes observed to drop off (Saumure and Bider 1996; Saumure and Livingston 1994; Ernst, pers. obs.).

TABLE 1. Seasonal incidence of algal colonization on *Chelydra serpentina* at White Oak, Lancaster County, Pennsylvania; percent incidence of turtles in parentheses. Total captures reflects the total numbers of turtles captured; some individuals of both sexes were captured more than one time.

Month	Total turtle capture	Male turtles	Female turtles	Immature turtles
March	12 (8)	1 (11)	0	0
April	31 (23)	6 (46)	0	1 (33)
May	48 (48)	17 (77)	6 (50)	0
June	101 (45)	20 (51)	18 (56)	8 (27)
July	42 (57)	15 (63)	5 (71)	4 (36)
August	15 (33)	3 (50)	1 (50)	1 (14)
September	25 (12)	2 (50)	1 (100)	0
October	6 (17)	0	1 (100)	0
Total	280 (39)	64 (54)	32 (53)	14 (15)

TABLE 2. Seasonal incidence of leech infestation on *Chelydra serpentina* at White Oak, Lancaster County, Pennsylvania; percent of turtles infested in parentheses. Total captures reflects the total numbers of *C. serpentina* captured; some individuals of both sexes were captured more than one time.

Month	Total turtle captures	Male turtles	Female turtles	Immature turtles	Total leeches	Leeches per turtle
March	12(0)	9 (0)	3 (0)	0	0	0
April	31 (23)	4 (31)	1 (33)	2 (33)	26	3.7
May	48 (35)	14 (64)	3 (25)	0	164	9.6
June	101 (32)	15 (38)	8 (25)	9 (30)	236	7.4
July	42 (38)	9 (38)	3 (43)	4 (36)	238	14.9
August	15 (33)	2 (33)	1 (50)	2 (29)	33	6.6
September	25 (12)	2 (50)	1 (100)	0	13	4.3
October	6 (0)	0	0	0	0	0
Total	280 (33)	55 (47)	20 (35)	17 (28)	710	7.8

According to Hall (1922), *Placobdella parasitica* can withstand exsiccation to 70.4% of its body weight (or approximately 92% of total body water). Continuous leech reinfestation must occur during at least May through August, as the turtle's habit of foraging in shallow waters probably brings them often into contact with the annelids (Readel et al. 2008).

A contingency table Chi-square test showed no significant difference (p = 0.19) between the rate of attachment on the two adult sexes, but the same test revealed a highly significant difference (p = 0.0009) between the rate of leech attachment on adults (sexes combined) versus that of immatures. The difference in numbers of leeches attached between adults and juveniles is probably at least somewhat explained by the smaller turtles' preference for shallow, warmer waters, and the recent hatchlings' habit of hiding on land while migrating from the nest site to water. In addition, the hatching period at White Oak is September-October and the increased number of hatchlings then entering the population contributed to the smaller overall percentage of infested immatures. The rate of attachment may also be related to the difference in surface area for attachment between adults and immatures. The mean number of leeches attached on those *C. serpentina* harboring them was 7.8, with the greatest numbers occurring in all sexes and age classes during June and July.

Problems may arise from leech parasitism. As *P. parasitica* take blood from a turtle, it is possibly weakened, which may contribute to a greater chance of it being depredated at White Oak, especially in smaller individuals. If the leech load is great, exsanguination theoretically could occur to such a degree that the turtle dies (but unreported), a greater potential problem in hatchlings or small immatures than for adults. The maximum numbers of leeches attached to White Oak *C. serpentina* were found on adults: 61 (male, 31.7 cm CL) and 40 (female, 31.7 cm CL). These patches of leeches were largely composed of a hermaphroditic adult and several small, recently hatched worms and probably caused little damage to adult turtles. Leeches of the genus *Placobdella* exhibit a specific pattern of parental care that definitely contributes to the parasite load of a turtle. After mating, the leech deposits a cocoon containing fertilized eggs on a solid surface, often a turtle's shell. The cocoon is cared for by the adult leech until the young emerge when the adult carries them to their potential first blood meal. In correspondence with the worm's life cycle, the leech load probably increases on turtles during April–July as more young emerge and the adults bring them to their first turtle-provided blood meal.

A second greater threat is from the leeches acting as vectors for parasitic protozoans from turtle to turtle. Leeches of the genus *Placobdella* are known intermediate hosts of several species of the sporozoan genera *Haemogregarina* and *Haemoproteus*, as well as the flagellate species *Trypanosoma chrysemydis*. *Placobdella parasitica* can transmit these parasites from an infected turtle to an uninfected one and between species of turtles within a turtle community (Siddall and Desser 1991, 1992, 2001; Woo 1969), much as *Anopheles* mosquitoes transmit malaria from human to human. Ernst and Ernst (1979) reviewed protozoan parasitism in North American turtles; see also the more recent papers by Siddall and Desser (1991, 1992) and Strohlein and Christensen (1984).

Snapping Turtles normally have a greater incidence of haemogregarine parasitemia than other sympatric turtle species (McAuliffe 1977; Siddall and Desser 1992). This has been attributed to the turtle's life style (Readel et al. 2008). It spends most of its time buried in mud in shallow water with only its eyes and nostrils exposed to air and often basks just beneath the surface of the water as opposed to more frequent aerial baskers, such as emydid turtles, whose longer periods of basking probably contribute to the removal of attached leeches (McAuliffe 1977).

Collection of data concerning attachment of both algal colonies and leeches should be included in future ecological and behavior studies of *Chelydra serpentina*. This is especially important as the incidence of leech attachment may be an indicator of the amount of protozoan parasitemia in a population.

Effectiveness of Leaf Litterbags for Sampling Stream-breeding Anurans: Tadpole Distribution, Composition, and Use

Amphibian population declines highlight the need to understand the limitations of sampling techniques and develop more effective means of assessing and monitoring. Leaf litterbags attract larval amphibians by mimicking natural substrate, while the bag's permeable exterior allows animals to pass freely in and out. Use of leaf litterbags in herpetofaunal surveys has been limited to sampling larval salamanders in the United States (e.g., Chalmers and Droege 2002; Nowakowski and Maerz 2009; Talley and Crisman 2007; Waldron et al. 2003). Leaf litterbags were used as early as the 1960s for examining benthic invertebrates (e.g., Anderson and Mason 1968; Crossman and Cairnes 1974; Hilsenhoff 1969). However, their employment has gained momentum in herpetofaunal research to improve our understanding of aquatic amphibians and larvae (e.g., abundance, as in Nowakowski and Maerz 2009) and reduce inter-observer differences that can affect visual encounter rates of more traditional sampling methods (e.g., dipnet sweeps: Shaffer et al. 1994). Additionally, litterbags can capture secretive or uncommon species that would be missed with more traditional sampling methods (Skelly and Richardson 2010).

Typically, tadpoles are sampled with dipnet sweeps, time-constrained searches, or opportunistic searches (Shaffer et al. 1994; Skelly and Richardson 2010). The usefulness of these techniques differs among observers based on effort and ability. Leaf litterbags minimize this type of error because investigators empty bag contents in the same way (Talley and Crisman 2007) or are trained to shake-out individuals without opening the bag using the same methodology between observers (see methods of Mackey et al. 2010). Therefore, scientists who are using untrained field assistants, or have a high turnover rate of field assistants may find their results more comparable among assistants when litterbags are employed versus another technique with a higher degree of inter-observer bias (e.g., dipnet sweeps: Shaffer et al. 1994).

Leaf litterbags create an artificial habitat to attract larval amphibians by mimicking natural leaf packs on the stream bottom (Skelly and Richardson 2010). Larvae are free to come and go from the litterbags, as long as their body size does not exceed bag mesh size. Mesh sizes vary among studies, and can bias results based on exclusion of larger larvae, prey, and predators when the mesh size is small (Waldron et al. 2003). The use of leaf litterbags has been limited to temperate zone stream-breeding salamanders (e.g., Chalmers and Droege 2002; Jung et al. 2000; Mackey et al. 2010) likely because it is a relatively new technique. Its application in the tropics may be useful in understanding anurans that breed in rocky streams where dipnet sweeps may miss tadpoles that retreat into crevices and naturally-formed leaf packs.

This study is the first to examine whether leaf litterbags can be used to sample tadpoles. We describe how tadpoles are distributed through time and space and among litterbags, including maximum densities recorded per litterbag. We use results of opportunistic searches for terrestrial adults to identify whether species composition resultant from tadpole-litterbag surveys yield reliable presence/absence composition estimates. Developmental stages are reported for the most abundant species so that biases for age-related selection using this method can be identified.

Site Description.— Cusuco National Park (CNP) is located in the Sierra de Omoa in northwestern Honduras. The Río Cusuco (15.494317°N, 88.2147°W) was sampled near the Visitor's Center at elevations from 1530–1560m. Water temperatures varied from 16–18°C during sampling events. River substrate is dominated by rocks, large boulders, and some sandy-bottom splash pools, with channel bends providing pools with low-flow areas where natural leaf litter and debris collects. Surrounding forest is Transitional Cloud Forest composed of *Pinus* and *Liquidambar* (Townsend and Wilson 2008), in the Lower Montane Wet Forest formation (Holdridge, 1967; McCranie and Wilson 2002). Most rainfall occurs from May/June through October/November, with April typically being the driest month (McCranie and Wilson 2002). Four anuran species within the study area could be encountered with leaf litterbags because they breed in streams (*Duellmanohyla soralia*, *Plectrohyla dasypus*, *Plectrohyla exquisita*, and *Ptychohyla hypomykter*; McCranie and Wilson 2002).

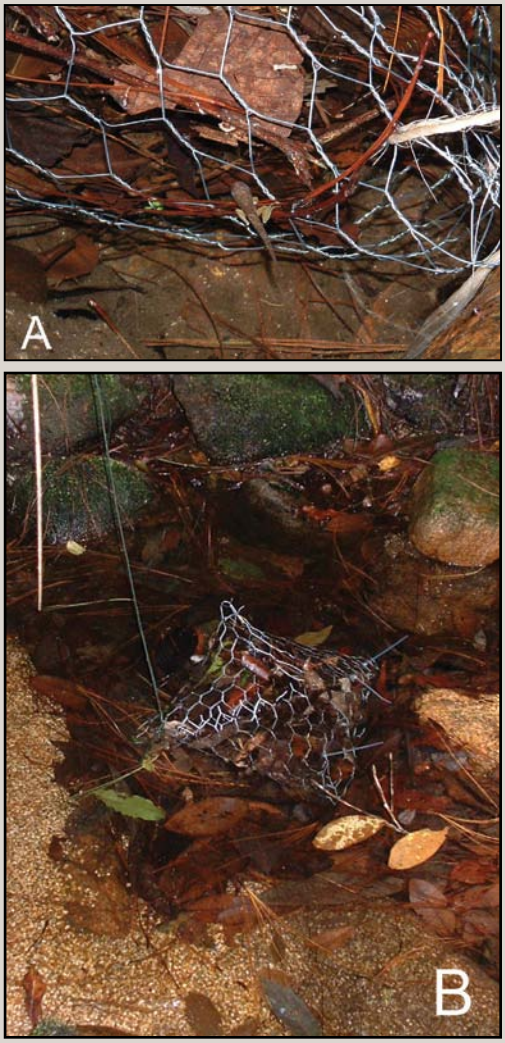

FIG. 1. A) A *Ptychohyla hypomykter* metamorph clings to vegetation at the edge of the leaf litterbag. Note the size of the metamorph relative to the mesh size of the litterbag. B) A leaf litterbag is visible in the middle of the photo, placed where leaf litter accumulates, secured to the bank with a piece of string.

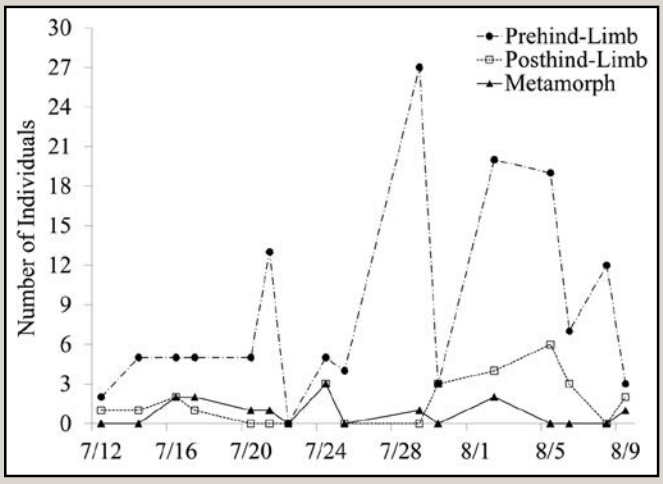

FIG. 2. Prehind-limb, posthind-limb, and metamorph developmental stages are represented in leaf litterbag samples for *Ptychohyla hypomykter* tadpoles.

Another stream-breeding anuran, *Lithobates maculatus*, has not been found in the park for several years, and is likely extirpated from the park (Townsend and Wilson 2008).

MATERIALS AND METHODS

The herpetological sampling expedition to Cusuco National Park had three overarching scientific objectives: daily monitoring of pitfall traplines for fossorial snakes, opportunistic searching to document all herpetofauna, and using leaf litterbags to document their effectiveness for sampling tadpoles. Pitfall traplines did not yield any stream-breeding adult anurans, so the specific methodology and results of that survey will not be discussed. Daily hikes through the forest to and from these traplines, however, were used to extend the stream-breeding adult frog species list when possible. Additionally, nighttime hikes were performed nearly every night (23 June–22 August 2005) to look for herpetofauna.

Leaf litterbags.— We designated five sample reaches in the Río Cusuco for litterbag placement. Six leaf litterbags were placed along each sample reach, with a total of 30 litterbags deployed in the river. Sample reaches were separated by approximately 35 m, and litterbag placement within sample reaches spanned approximately 20 m. Litterbags were not evenly dispersed within sample reaches because they were employed only in areas where there were pre-existing pools for leaf litter accumulation. Leaf litterbags were checked every 3–5 days from 11 July–8 August 2005, or exactly nine times for each leaf litterbag. This 3–5 day interval between sampling events allowed time for recolonization by tadpoles.

We constructed litterbags using easily obtainable materials (i.e., "chicken wire"). Additionally, we knew that our target species maximum larval size would not exceed the mesh size of the chicken wire (e.g., Fig. 1a), and, therefore, would not be excluded based on body size. Leaf litterbags were constructed by cutting 0.45 × 0.45 m (1.5 × 1.5 ft) squares, securing the corners together with plastic ties to form an 'envelope' shape ($V \cong 0.0054\ m^3$). Litterbag size was based on Waldron et al. (2003), who found medium and large litterbags to be most effective in small streams. The bag interior was filled with litter debris from the stream edge and bottom. To secure leaf litterbags in place, rocks of approximately equal mass were placed in the interior to weight the bags. Using twine, each leaf litterbag was tied to a nearby tree to prevent displacement and loss. During the 2004 field season, litterbags were not secured to the banks, and were displaced during a heavy storm. Leaf litterbags were placed in the river where debris naturally accumulated (Fig. 1b).

Upon retrieval, litterbags were rapidly pulled from the stream and placed into a plastic container to prevent escape of tadpoles. No tadpoles were ever observed escaping before the litterbags were placed in the plastic tub. Leaf litterbag contents were then placed in a dipnet to drain water. Tadpoles were placed in water-filled plastic bags for field identification. Tadpoles were identified in the field with a hand lens to determine species (based on McCranie and Wilson 2002) and Gosner (1960) developmental stage. Tadpoles with mouthpart malformations and those for which species identification was not certain in the field were collected and preserved for further analysis (N = 39); they will be deposited at Florida Museum of Natural History upon completion of future genetic analyses. All captured anuran larvae were classified into prehind-limb (Gosner Stage 25), posthind-limb (Gosner Stages 26–41) or metamorph (Gosner Stages 42–46) developmental stages.

Terrestrial Surveys.— Opportunistic searching during daytime and nighttime hikes was used to determine the presence or absence of adults of each species. All trails mentioned in Townsend and Wilson (2008) were used for daytime and nighttime hikes, as well as hiking along the Río Cusuco itself. As a minimum estimate, at least 6 h per 24 h day were spent searching for herpetofauna (morning trapline work: 3 h, afternoon litterbag surveys: 2 h, and night hikes: 1–2 h). Methodology included visually searching for herpetofauna in vegetation, beneath fallen logs and rocks, within the upper layers of soil, on boulder surfaces in the Río Cusuco, and within overhanging vegetation near river edges. We use qualitative comparisons of presence/absence data for adult species from terrestrial opportunistic visual encounter surveys with tadpole species presence/absence data from leaf litterbag surveys.

RESULTS

Tadpole distribution.—All but four litterbags yielded at least one individual. On average, 4.6 tadpoles (+/- 0.3 SE; range 0–16) were captured during 40 litterbag sampling events, where a sampling event is equivalent to checking an entire litterbag reach. Of the litterbag checks, where examination of one leaf litterbag equals one "litterbag check," most yielded zero (61.3%) or one tadpole (20.8%) (Table 1).

Adult and larval species composition.—Of the stream-breeding anurans in Cusuco National Park, the adult opportunistic survey found four of five possible species: *D. soralia, P. dasypus, P. exquisita,* and *P. hypomykter*. We found tadpoles of these same four anuran species in the litterbags (*D. soralia* [N = 1], *P. dasypus* [N = 4], *P. exquisita* [N = 1], and *P. hypomykter* [N = 175]) (Table 2). We did not detect one of the stream-breeding frog species known to occur in Cusuco National Park, *L. maculatus*, in any of our surveys. The visual encounter survey (VES) lasted for eight weeks, while the corresponding leaf litterbag survey (LLS) lasted for five weeks (Table 2). For both VES and LLS, *D. soralia* and *P. exquisita* were found at low frequencies. In contrast, *P. dasypus* and *P. hypomykter* were found with greater frequencies (Table 2). We were unable to identify one tadpole to species because of severe mouthpart malformations.

Developmental stage composition.—We collected only one tadpole of both *D. soralia* and *P. exquisita*. We found all three developmental categories of *P. dasypus* throughout the study. The majority of *P. hypomykter* tadpoles captured belonged to the prehind-limb developmental stage (N = 136), followed by posthindlimb (N = 26) and metamorph (N = 13) stages (Fig. 2).

DISCUSSION

We used leaf litterbags in a swift-flowing montane stream in Honduras to sample tadpoles of four stream-breeding species. As with previous larval salamander litterbag survey results (Talley and Crisman 2007), we found most litterbag checks contained no tadpoles. On the other hand, nearly 40% of the litterbag checks contained at least one individual (Table 1). Although the litterbag volume we used in this study (V ≅ 0.0054 m^3) was greater than that used by Talley and Crisman (2007) (V ≅ 0.0018 m^3), the number of individuals we found per litterbag was similar. If a litterbag contained at least one individual during a litterbag check in either study, it typically yielded only one or two individuals, with a maximum of nine salamander larvae (Talley and Crisman 2007) and seven tadpoles in this study (Table 1). The social biology of these species has not been studied, but *D. soralia* is the only species we detected known to aggregate, swimming upside down at the surface (McCranie and Wilson 2002), while at other times found separately on the stream bottom (Townsend and Wilson 2008). Because the other species are not known to aggregate, and were not observed aggregating in this study, the number of individuals we captured might simply represent natural tadpole densities for the given litterbag size. Additionally, these capture values might be affected by the amount of colonizable area and territory size requirements, inter- and intra-specific competition, and food source availability (Chalmers and Droege 2002; Fraser 1976; Talley and Crisman 2007; Waldron et al. 2003) because litterbag design mimics natural conditions.

Tadpoles of the four anuran species differed markedly in frequency of occurrence in litterbags, perhaps resulting from different larval periods, alternate microhabitat uses, or an over-abundance of the most common species. Honduran tadpoles typically metamorphose into adults at the end of summer months, with timing of emergence from water varying among species (McCranie and Wilson 2002; Townsend and Wilson 2008). The most commonly observed treefrog in Cusuco National Park is *P. hypomykter* (Townsend and Wilson 2008). Calling males, amplectant pairs, and tadpoles have been found in March, April, June, July, August, and September (Townsend and Wilson 2008). *Ptychohyla hypomykter* tadpoles made up 96.2% of those encountered in this study. Previous studies with larval salamanders found

TABLE 1. Tadpole distribution among leaf litterbags indicates that nearly half of those litterbags checked contained at least one tadpole, and as many as seven.

Individuals per litterbag	Number of litterbag checks	Percent of total litterbag checks (%)
0	147	61.3
1	50	20.8
2	24	10.0
3	8	3.3
4	3	1.3
5	3	1.3
6	2	0.8
7	3	1.3
Total	240	

TABLE 2. Species presence determined by terrestrial visual encounter surveys (VES) of adults and metamorphs, and leaf litterbag surveys (LLS) of tadpoles and metamorphs. 'X' denotes species presence. Shaded areas indicate survey weeks when litterbags were not sampled. The first survey week was 23–30 June, the rest following without interruption.

		Survey Week

D. soralia	LLS				X				
	VES	X							
P. dasypus	LLS				X		X		
	VES	X	X	X		X	X	X	X
P. exquisita	LLS						X		
	VES						X		
P. hypomykter	LLS			X	X	X	X	X	
	VES	X			X	X	X	X	X

similar distinctions in capture rates between species, with 95% of the total captures being larvae of a single salamander species (*Eurycea cirrigera*) (Talley and Crisman 2007). The relatively short duration (11 July–8 August 2005) might have contributed to the lower capture rates of some species if this study period did not encompass their larval periods. For example, Townsend and Wilson (2008) reported transformed *P. dasypus* on streamside boulders and vegetation during June and July; this indicates that the startup date of our study in mid-July was on the tail end of the larval period for *P. dasypus*. The likelihood of finding tadpoles in litterbags is reduced when their natural behavior does not favor leaf-pack colonization. For example, tadpoles of *P. dasypus* and *P. exquisita* often are observed on rocks in fast-flowing portions of stream, whereas *D. soralia* tadpoles tend to school near the surface or in the water column in deeper pools (McCranie and Wilson 2002; Townsend and Wilson 2008). Therefore, tadpoles of these three species might not normally utilize submerged leaf litter as preferred microhabitat. The prevalence of *P. hypomykter* tadpoles in our samples might be explained by any or all of these factors.

We determined that leaf litterbags contained tadpoles of all anuran species presumed to use the Río Cusuco based on prior knowledge of their reproductive strategies (Townsend and Wilson 2008) and the results of opportunistic terrestrial surveys conducted in this study. Based on presence/absence assessment of tadpole and adult species, we found that our study identified tadpoles in the leaf litterbag survey of the same species as adults in the terrestrial survey (*D. soralia, P. dasypus, P. exquisita,* and *P. hypomykter*) (Table 2). Previous studies dealing with salamander species presence/absence composition in leaf litterbags also found the same larval species as adults known to the area (e.g., Pauley and Little 1998; Chalmers and Droege 2002; Talley and Crisman 2007; Waldron et al. 2003).

We found representatives of all three major developmental stages (prehind-limb, posthind-limb, and metamorph) in our litterbag samples throughout the duration of our study period for *P. hypomykter* tadpoles (Fig. 2). The prehind-limb developmental stage (S 25) was most common (78%) in the tadpoles of *P. hypomykter* sampled, which likely reflects the abundance of this stage in the entire population. The distribution of tadpole stages (Fig. 2) does not appear to reflect an aging trend, where younger (prehind-limb) tadpoles were collected earlier in the survey and older (posthind-limb and metamorph) tadpoles were collected later in the survey. Therefore, the difference in relative abundance among developmental states is due either to bias in the capture probabilities from the sampling technique or is reflective of real differences in tadpole developmental stage structure.

Because our sample sizes were limited for some species, a decreased sampling effort could have missed *D. soralia* and *P. exquisita* tadpoles all together. Future studies employing leaf litterbags should first address whether tadpole species of interest are likely to be found in leaf litter. Additional sampling methods might be necessary for species that are difficult to detect, particularly if they are of critical conservation concern. Next, future researchers should choose sample sites that have natural leaf litter accumulation. Finally, they should pick the number of litterbags deployed, and duration of litterbag deployment based on the needs of their study. For example, if only a handful of tadpoles are desired for study, then fewer litterbags could be used. We found unequal litterbag occupancy between stream reaches, but know that when six litterbags were used, we detected an average of 4.6 tadpoles within that reach.

We provide information on the reliability and use of leaf litterbags, a technique typically used to monitor larval salamanders, for sampling tadpoles in the tropics. Use of this sampling technique on a wide range of other stream-dwelling amphibians worldwide could contribute to assessment of natural populations since amphibians are declining worldwide (Stuart et al. 2004). We demonstrate herein that leaf litterbags can be used to sample stream-breeding tadpoles in a swift-flowing montane stream. If a tadpole's association with natural leafpacks in the stream is unknown, the species is of particular conservation significance, or leaf litterbags do not yield any encounters, then an additional sampling method may be necessary.

Acknowledgments.—Roberto Downing M. was of invaluable assistance in arranging the logistics our work, and helping to obtain collection and export permits. Conrado Gonzáles, Martha Moreno, Ibrahim Padilla, and Carla Cárcamo of the Departamento de Areas Protegidas y Vida Silvestre (DAPVS) of the Administración Forestal del Estado Corporación Hondureña de Desarrollo Forestal (AFE-COHDEFOR), Honduras, generously provided permission to collect and export scientific specimens; fieldwork was carried out under permits issued to LDW, JHT, and James R. McCranie. Fieldwork in Honduras during 2004 and 2005 was supported by Operation Wallacea and the Reptile and Amphibian Conservation Corps (RACC). Field assistance from the herpetology team was provided by T. Lynette Plenderleith, James C. Nifong, Douglas C. Fraser, additional scientists located at our Base Camp, and dozens of volunteers from the Operation Wallacea Honduras Forest Project. Doña Gladys Fasquelle, of the Pastor Fundacíon Hector Rodrigo Pastor Fasquelle, San Pedro Sula, Honduras, kindly stored specimens associated with this project over the course of late 2004 and early 2005. Thomas L. Crisman provided support to BLT throughout the data analysis process. Karen R. Lips and two anonymous reviewers provided insightful comments on an early version of this manuscript.

A Device for Restraining Gopher Tortoises (*Gopherus polyphemus*) During Blood Extraction

Collection of blood or other biological samples from Gopher Tortoises (*Gopherus polyphemus*) is necessary for assessments regarding health status, disease, and genetics. Researchers use a variety of techniques for restraining tortoises during sample collection, sometimes having one person draw the blood while a second person holds the tortoise. However, budget and manpower constraints do not always allow for two people to be present during blood extraction, especially in remote field situations. Some researchers place the tortoise on a large metal coffee can while drawing blood from the brachial vein in the forelimb (G. McLaughlin, pers. comm.); others restrain the tortoise in their lap or on a truck tailgate while extracting blood subcarapacially (P. Moler, pers. comm.). These techniques can be effective if the tortoise is not excessively active. The need for one person to be able to quickly and effectively extract blood under field conditions from gopher tortoises of varying activity levels was the impetus for constructing a portable tortoise restraint device (TRD).

The TRD is designed to be used with a pickup truck but can be modified for placement on other surfaces such as a portable field table. Two 12-in. lengths of pressure-treated two-by-two (a standard U.S. lumber product that actually measures 1.5 × 1.5 in.) are laid perpendicular to the back edge of the open tailgate, so that the tips are flush with the tailgate's edge. The outside distance between these parallel wood pieces is 13.5 in. Measurements are given in English units to correspond with lumber and fastener sizes in U.S. hardware stores. Two holes (3/8-in. diameter) are drilled through the side of each of the lengths of two-by-two (approximately 2 in. from each end) to facilitate attachment of the TRD to the truck (see below; Fig. 1). Two additional 3/8-in. holes are drilled from the top through each of the two lengths of two-by-two (approximately 1 in. from each end), with corresponding pilot holes drilled in the tailgate so that the wood can be secured to the tailgate with 2-in. long sheet metal screws. This completes the tailgate mount and support for the TRD (Fig. 1). To avoid drilling holes into a truck tailgate, C-clamps or cargo straps could be used to secure the TRD; alternatively, the TRD platform could be attached to a heavier base for use on tables, counters, or tailgates.

The outside distance (13.5 in.) between the two lengths of two-by-two mounted on the truck tailgate provides the basis for the dimensions of the TRD platform. Two 12-in. lengths of two-by-four (another U.S. standard lumber product, measuring 1.5 × 3.5 in.) lying on their shorter edge and positioned 13.5 in. apart at the inside, serve as the base of the platform (Fig. 1). Four holes (3/8-in. diameter) drilled into the sides of the base correspond to the four holes drilled into the two lengths of two-by-two previously attached to the truck. Four 4-in. bolts pushed through these holes secure the TRD to the truck during use (Fig. 1). A piece of ¾-in. plywood is cut to a width of 12 in. and a length of 16.5 in., laid atop the pieces of two-by-four flush to its ends and outer edges, and attached to them with decking screws. Two additional lengths of two-by-four, each 16.5 in. long, are sawed into trapezoids that have an outer angle of 60° and placed on edge atop the plywood base along the 16.5-in. side (Fig. 1). These pieces are attached through the bottom of the plywood with decking screws. Another piece of ¾-in. plywood measuring 12 × 12.5 in. is then attached to the top of the trapezoidal pieces with decking screws (Fig. 1). This completes the basic TRD platform. If desired, 3/8-in. holes may be drilled into the rear left quadrant of the upper plywood platform to provide storage for the four bolts when the TRD is not installed on the tailgate. Additionally, metal handles may be attached to each side of the TRD base to facilitate its placement and removal.

An 8-in. block of four-by-four serves as the pedestal on which the tortoise is placed during blood extraction (Figs. 1, 2). This block supports the center of the plastron and prevents

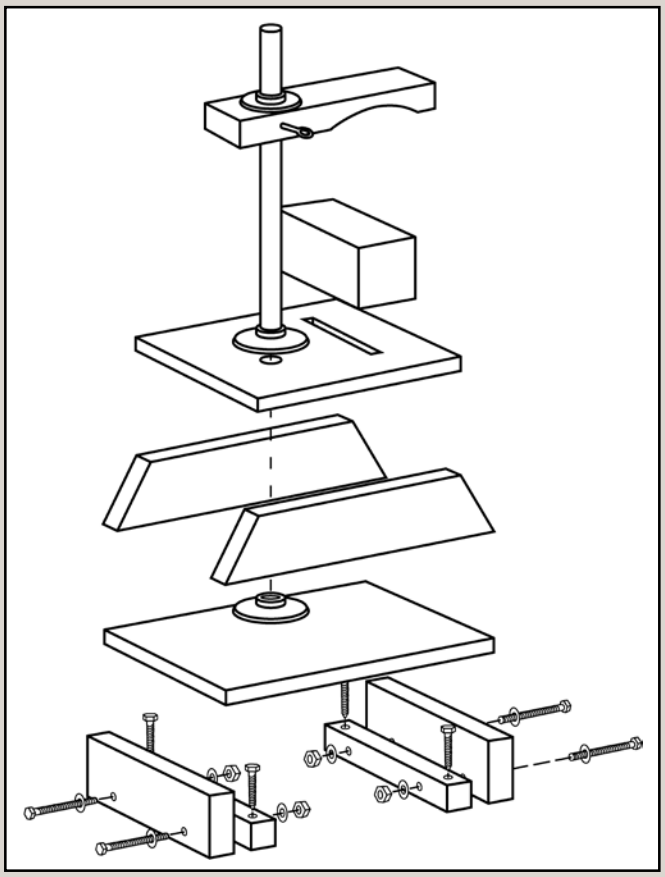

FIG. 1. Schematic illustration showing how parts of the tortoise restraint device come together.

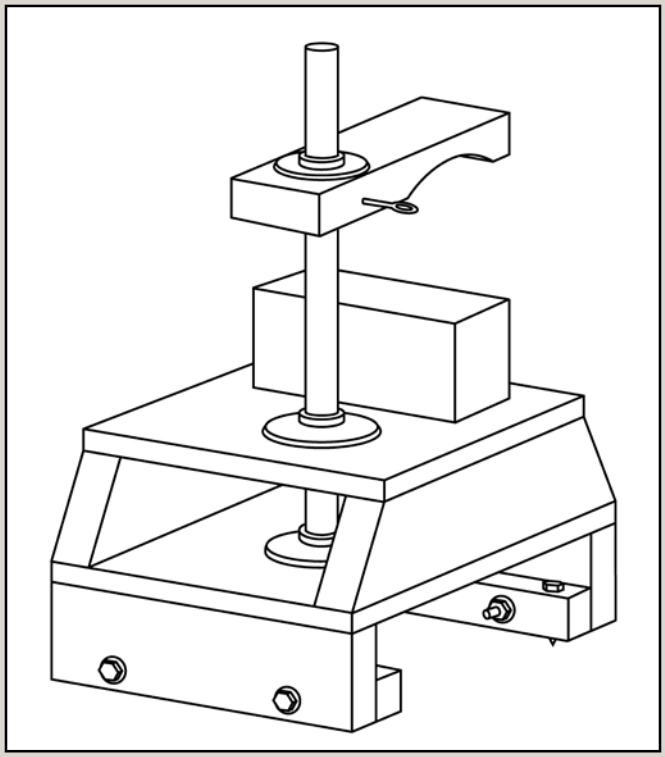

FIG. 2. The tortoise restraint device, lateral view.

FIG. 3. Radio-instrumented Gopher Tortoise in the restraint device. Note both the eye bolt that allows vertical adjustment of the clamp to fit individual tortoises and the bungee cord that goes between eye screws on the clamp and base to further secure the tortoise.

the tortoise from gaining traction with its feet (Fig. 3). Because of variation in the size of tortoises, the pedestal must be adjustable in relation to the fixed clamp that holds the tortoise in place (described below). A 3/8-in.diameter double-ended screw/bolt is placed in the center of the bottom of the block of four-by-four (the threaded end screws into the block, leaving the bolt end exposed). A 7-in. slit slightly wider than the bolt is cut into the top of the TRD platform 3 in. from the right side (Fig. 1). By inserting the bolt through the slit and securing it with a washer and wing nut, the block can be positioned fore and aft of the clamp. A block of four-by-four 6 in. long may be cut if desired to a width of 2.5 in. to accommodate smaller tortoises. Foam rubber pads, about ¼-in. thick, are hot-glued to the tops of these blocks to reduce slippage of the tortoise.

To create the clamp that holds the tortoise in place, a 1-in. diameter hole is drilled through the top of the TRD platform approximately 4 in. from the left side and 5 in. from the front. A ¾-in. galvanized female pipe stand is secured with screws to the bottom piece of plywood directly under the hole in the TRD platform. A ¾-in. diameter pipe approximately 18 in. long and threaded at both ends is inserted through the hole and screwed into the pipe stand (Figs. 1, 2). The top part of the clamp is made from a 15-in. length of two-by-four through which a 1-in. hole has been drilled in the center of the broad edge (approximately 3 in. from one end). The wood is placed on the pipe, inserting it through the hole and moving it down until it comes to rest on the block. An arc that approximates the shape of a tortoise shell is sketched on the narrow edge of the 15-in. piece, with the highest point of the arc falling directly over the center of the block (Figs. 1, 2). The arc is then cut out of the 15-in. piece with a scroll saw, leaving the wood thick enough (at least 5/8 in.) that it is not weakened. Because the area within the arc will be contacting the tortoise's shell, it is lined with soft foam hot-glued to the wood. Three additional 1-in. female pipe stands are fastened with screws to reinforce the pipe, one above the hole in the 15-in. piece, one below that hole, and one on the top tier of the platform (Figs. 1, 2).

With a ½-in. drill bit, a hole is drilled between the narrow edge of the 15-in. clamp and the 1-in. pipe hole. A threaded bolt insert

is screwed into this hole and a large 3/8-in. eye bolt is screwed into the insert. When threaded completely through the hole, the bolt makes contact with the pipe and allows the clamp to be secured in any vertical position along the length of the pipe (Fig. 3). Medium eye screws are fastened to the right end of the clamp and the lower right two-by-four of the base of the TRD platform. A bungee cord stretched between these two eye screws adds further strength to the clamp when a tortoise is in the TRD (Fig. 3).

The TRD should be coated with a water sealer to keep urine, feces, and blood from soaking into the wood. Additionally, the TRD should be rinsed with water to remove organic debris and then cleaned with a mild bleach solution (1:20 dilution of 5% household bleach in water) or a disinfectant such as Trifectant after each tortoise is sampled.

Although originally designed for extracting blood from the brachial vein of a tortoise's forelimb, this adjustable device can be used to restrain tortoises for other types of sample or data collection, assessment of clinical signs of disease, and attachment of radio transmitters (Fig. 3). The TRD safely secures the tortoise, allowing access for sampling while precluding excessive handling and manipulation. We found the TRD to be effective, practical, and versatile.

Acknowledgments.—We thank L. French and A. Holman for their assistance with illustrations. We have complied with all applicable animal care guidelines, especially those involving restraint of wild animals as outlined by SSAR. Retention of Paint Markings for Individual Identification of Free-ranging Basking Aquatic Turtles (Suwannee Cooters, *Pseudemys concinna suwanniensis*)

Marking animals is often essential in ecological studies (Krebs 1999), but different taxa pose various challenges in applying marks with suitable retention periods (see Silvy et al. 2005 for an overview of methods). The bony turtle carapace provides convenient opportunities for permanent individual marking, such as the shell notching technique introduced by Cagle (1939). However, basking aquatic turtles (such as *Chrysemys*, *Graptemys*, *Pseudemys*, and *Trachemys* in North America) quickly fall from their platforms into the water and swim away rapidly when approached, making it impractical to read notches.

Methods that allow for distant recognition without capture, thereby resulting in minimal disturbance to individuals, are highly desirable. Although paint marking has been used in population studies of aquatic turtles (e.g., Jones and Hartfield 1995; Kramer 1995; Selman and Qualls 2008, 2009), assumptions of paint retention that are critical in interpreting recapture sightings are frequently untested. As part of a more comprehensive study of movement patterns and habitat use, we applied paint marks to an emydid species from the southeastern USA, the Suwannee Cooter (*Pseudemys concinna suwanniensis*). These large turtles (maximum carapace length = 437 mm; Pritchard 1980) are strong swimmers and inhabit various riverine habitats, where they spend extensive time basking above water (Jackson 2006; Ward and Jackson 2008). Here, we report observations on the retention of paint marks on free-ranging Suwannee Cooters to evaluate the utility of this method for monitoring this species.

Methods.—The study site encompassed a 3.4-km stretch downstream from the US Highway 441 bridge over the Santa Fe River, ca. 4 km downstream from where the river reemerges above ground from the Floridan Aquifer (Alachua and Columbia counties, north-central Florida, USA). Most of the study site and its surroundings are managed by River Rise Preserve State Park, part of the largest publicly protected area along the Santa Fe River. Within the preserve human take of turtles is illegal. Although the river water is normally dark brown from tannins, a drought in 2006–2007 lowered the river level, substantially resulting in clear water with good visibility during the study. Kornilev (2008) and Kornilev et al. (2010) describe the study site in more depth.

From 18 to 23 May 2007, we snorkeled and hand-captured 50 Suwannee Cooters (23 males, 25 females, 2 juveniles; mean straight carapace length [SCL] = 288 mm; range 164–375; SD = 53). After recording standard morphometric measurements, we removed algae from the dorsolateral side of the carapace, dried it, and detached any shedding scutes in order to facilitate paint retention. We then painted a unique identifying number on each side (Fig. 1). We used a white, non-toxic, oil-based paint marker designed for rugged industrial use (563 Speedry, Diagraph, Marion, Illinois, USA; price: US $3/marker). The width of the paint lines was 0.5–1.0 cm and the complete 2-digit number was usually ca. 7 × 7 cm. Each marker was sufficient to mark 30–50 individuals. In addition, we attached in the field a temperature-sensitive datalogger (iButton; Maxim Integrated Products, Sunnyvale, California, USA) on the marginal scutes above the right rear leg of each turtle (Fig. 1; Kornilev 2008). We coated the iButtons in black plastic, which increased their height to ca. 9 mm and radius to ca. 11 mm. Turtles were released at the point of capture after the paint dried completely (ca. 10 min).

We conducted intensive resampling for 60 days after the turtles were marked. During 26 visits to the river, one or two

observers surveyed the length of the field site by kayak 3–4 times per week. With the aid of compact binoculars (7 × 35 power), we searched for, observed, and attempted to identify individually both basking and swimming turtles. Since the iButtons were usually visible from a distance, we could often determine if a turtle had been previously captured even when the painted numbers had worn off. Resighted animals that could not be unambiguously identified were classified as "Unidentified."

Visits to the field site between July 2007 and April 2008 were less intensive and we present here only incidental results from that period. While attempting to retrieve iButtons, we captured 39 additional, unmarked turtles. Some numbers quickly wore off or were too small and difficult to detect, so we subsequently increased the line width of the paint marks to 1–2 cm and the overall mark size to ca. 12 × 12 cm to improve detection and paint retention. After July, additional limited sampling also was conducted in the 4 km upstream of the US 441 bridge (Kornilev 2008; Kornilev et al. 2010).

Results.—Within the two months of intensive resampling, 41 turtles (82%; 16 males, 23 females, and both juveniles) were positively identified at least once. We successfully identified turtles 191 times, excluding daily resightings. Individuals were identified more than once per day on 44 occasions, primarily during the first 30 days. Marked individuals could not be identified on 125 occasions, principally due to deterioration of the paint marks, with just a few turtles escaping prior to identification. We observed a turtle with an iButton but without distinct numbers as early as six days post-marking (Fig. 2).

The mean number of days from the initial capture to the last identification or recapture was 22.75 (range: 4–52, SD = 10.98; N = 41). No significant difference between sexes was detected (ANOVA: $F(1, 37) = 1.019$, $p = 0.319$, $= 0.05$; Kolmogorov-Smirnov & Lilliefors test for normality: $p > 0.2$ for each sex).

The use of thicker and larger paint marks applied on the additional turtles captured after July 2007 resulted in discernible marks for longer periods of time than the thin marks initially used. On 31 March 2008, YK observed two turtles with faint paint marks but failed to identify them before they entered the tannin-stained water. The last date on which we painted marks was 28 September 2007; therefore marks could be retained for at least 186 days (>6 months).

Numbers on basking turtles could be identified from 20–30 m with the use of the compact 7 × 35 binoculars. Although water clarity varied slightly across the study site and period, swimming turtles often could be identified up to 3–4 m horizontal distance away from the observer and at depths of 2.5 m. Swimming turtles were occasionally detected because the paint number was observed prior to the turtle itself being visible.

Discussion.—Our results on paint mark retention are concordant with published reports of similar studies on freshwater turtles. Kramer (1995) reported paint mark retention for 1–3 months on Florida Redbellied Turtles (*P. nelsoni*) using rubberized or epoxy paint. Jones and Hartfield (1995) also reported retention rates of up to three months for *Graptemys oculifera*. Selman and Qualls (2008, 2009) did not address the question of mark retention in estimating population size of *G. flavimaculata* and *G. gibbonsi*; they did note flecks of paint on several individuals recaptured 8–14 months after applying a fluorescent spray paint, but the paint was probably not enough for a successful "resighting" (W. Selman, pers. comm.). However, all of the *Graptemys* studies noted that mark-resight surveys were completed within two weeks of the first individual being paint

FIG. 1. Representative paint mark and iButton (circled) on a female Suwannee Cooter (SCL = 365 mm). The inset shows an enlarged coated iButton (ca. 11 mm) next to a US quarter coin.

marked in order to prevent losing marks; similar population estimates across years for these studies indicate that paint marks were persistent shortly after application and that mark-resight is a valid population estimation tool. The differences in paint retention between the studies could be attributed to varying ecological factors (e.g., water chemistry, species behavior) as well as the properties of the assortment of brands of paint used. Similar to previous results, our study suggests that wide paint marks can be used for more than 1 month to monitor at least some individual turtles with minimal disturbance, but that decreased paint retention limits the effectiveness of this technique for longer-term studies.

In our study, abrasion, shedding of scutes, and rapid algal growth on the carapaces of some individuals reduced paint retention and detection. However, the width of the paint lines was not the only determining factor for the rate of paint loss. For example, individual #23 had thinner number lines painted than other turtles, but its marking lasted for 52 days, longer than on most other individuals. Although we documented extended retention for paint marks especially applied after July, this might have reflected decreased turtle activity (leading to less abrasion of the paint against floating vegetation, tree logs, etc.) and scute shedding during the cooler fall months when growth is slower than in summer (Huestis and Meylan 2004). The extent of algal colonization and shedding of scutes as well as the propensity to disperse likely reflect individual differences among turtles (Kornilev et al. 2010).

Suwannee Cooters are strong swimmers and dispersal beyond the study site may have led to our inability to observe some marked turtles (see Kornilev et al. 2010). For example, the paint marks on individual #44 started to fade when last seen 45 days after capture; on individual #46, the numbers were still well preserved and easy to read on the last observation 33 days after paint was applied. However, both individuals presumably emigrated from the field site since they were never observed or captured again even during several surveys outside of the study site.

The choice of paint color that provides the best visibility should be considered carefully. In our experience the white

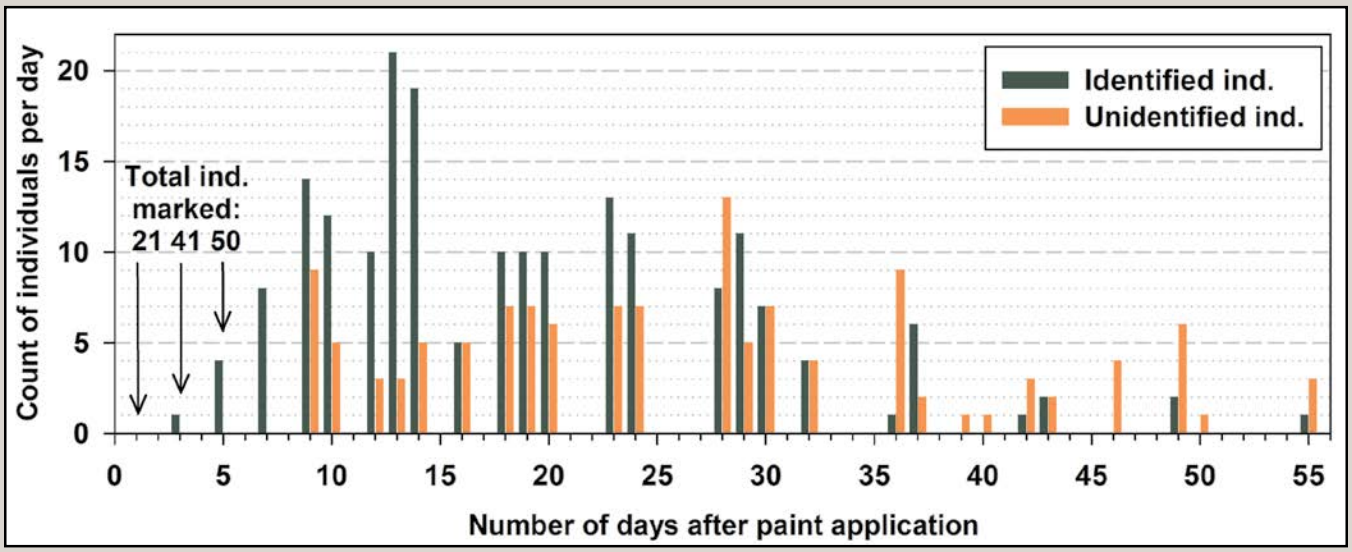

FIG. 2. Daily counts of identified individuals and unidentified but marked turtles based on double marking (individual paint marking and external temperature logger) of 50 turtles. "Unidentified" turtles lacked a clear paint mark but had a visible iButton or in a few instances escaped before a positive identification could be made. Turtles were marked 18–23 May 2007 (days 0–5).

paint was clearly visible in most instances against the contrasting black carapace of the *P. c. suwanniensis*. However, the glare from a dry carapace painted with orange made turtle identification problematic in full sunlight; blue or green marks could be difficult to distinguish against a background of vegetation along the river (R. Jones, pers. comm.).

The potential of differential fleeing responses by basking turtles to watercraft or observers on the bank should be considered and/or tested in mark/resighting studies or surveys. Habituation to boat traffic, interspecific differences, or stress caused by the marking procedure might skew the results, even when comparing data on a single species among sites within the same river (R. Jones, pers. comm.). In our study, turtles exhibited a range of behavioral responses, sometimes allowing us to approach them to less than 2 m, while at other times fleeing when observers were more than 50 m away. Observers might also be biased and initially focus their attention on counting marked turtles while conducting boat surveys, during which time unmarked turtles might escape without being recorded. Combining both spotting scope surveys from a hide with boat observations could minimize observer bias, increase detection probability, and provide for more accurate estimates of population parameters.

To improve mark retention and resightability, we suggest that researchers 1) completely remove algae and loose scutes from the carapace prior to marking, 2) thoroughly dry the shell before painting, 3) use wide paint marks with more paint, and 4) combine appropriate paint colors on the same individual while varying the position of the number on the carapace to facilitate identification even under suboptimal conditions.

A question not addressed by our study is whether the presence of highly visible marks increased depredation either directly on adults or indirectly on nests or females while depositing eggs. We do not have reason to suspect increased predation or take by humans on individuals during our study. Only a few basking alligators were observed diurnally, when marks were most detectable and turtles were susceptible to visual predators. Although alligator tooth marks have been observed on a few turtles in the river, none of our paint marked turtles bore fresh tooth marks or wounds that post-dated original capture and paint application. Still, we advise against application of paint on hatchlings and juveniles (SCL < 100 mm), since they favor spending time in cryptic microhabitats as an antipredatory strategy (Jackson and Walker 1997; Kornilev 2008).

Aside from the scientific information we collected, the visible paint numbers sparked the interest of recreational boaters on numerous occasions on the river and led to a short note in a local newspaper (Reinink 2008). The potential for publicity to serve a negative purpose, such as facilitating human harvest, should be considered prior to marking animals (e.g., Heinrich et al. 2010). However, publicity may also serve a positive purpose by raising public awareness of conservation issues. If properly planned, citizen scientists might even be trained to increase the amount of data collected.

Our experience supports the view that individual paint marking is suitable for short-term collection of ecological data and monitoring of basking turtles. It also provides an inexpensive tool for successful management and conservation, but retention, behavioral responses, and length of study need to be considered thoroughly before applying this technique and interpreting results.

Acknowledgments.—YK thanks his advisor C. K. Dodd, Jr., and his committee (H. Lillywhite, M. Nickerson, and G. Johnston). We are indebted to J. Woods and the Santa Fe Canoe Outpost, the employees of O'Leno and River Rise Preserve State Parks, and numerous volunteers for their support. R. Jones, W. Selman, M. Shirley, N. Tzankov, A. Westerström, and an anonymous reviewer provided helpful comments that greatly improved the manuscript. The PADI Foundation and the Reptile and Amphibian Conservation Corps provided financial support. The study has been approved by UF IACUC protocol E885, FWC permit WX07166, and FL DEP permit 04230712.

Blood Sampling in Testudinidae and Chelidae

Blood sampling is among the most common procedures in vertebrate studies. When done correctly, it may be less invasive than taking other tissues. In the case of DNA analysis, rather small amounts of blood are necessary, although the required amount may be larger for physiological studies.

An easy sampling technique is important for obtaining blood from chelonians for a variety of purposes, such as genetic analyses and clinical pathology diagnostics. Several blood sample sites have been described in chelonians, including heart, veins (jugular, brachial, ventral, femoral, coccygeal, or scapular), brachial artery, orbital sinus, a sub-carapacial venipuncture site, retro-orbital space, and trimmed toe-nails (Avery and Vitt 1984; Bulté et al. 2006; Dessauer 1970; Hernandez-Divers et al. 2002; Jacobson 1987; Rogers and Booth 2004; Stephens and Creekmore 1983; Ulsh et al. 2001). Some sampling methods have disadvantages, such as higher risk of infection (Strik et al. 2007). The orbital sinus has been used for collecting small volumes of blood through capillary tubes (Nagy and Medica 1986), however, this method results in dilution of the blood sample with extracellular fluids and secretions, which may alter the composition of plasma, affect the volume of cellular components, and result in incorrect interpretation of biochemical data. Because lymphatic systems are well developed in chelonian forelimbs and tails (Ottaviani and Tazzi 1977), obtaining blood samples from sites near the lymphatic system may result in hemodilution with lymph (Rohilla and Tiwari 2008).

Most published techniques have been applied in long-tailed species such as *Graptemys geographica*, *Trachemys scripta*, *Macrochelys temminckii*, and marine turtle species (Bennett 1986; Bulté et al. 2006; Roman et al. 1999; Ulsh el al. 2001; Wibbels et al. 1998). However, the tail is very short in some species, e.g., in the genera *Chelonoidis* and *Phrynops*. This may cause some practical problems in blood sampling when utilizing the tail vein, such as sample contamination, because of the fecal discharge used as a defense mechanism and because animals may be difficult to hold firmly with recommended devices, such as those described for *Trachemys scripta* (Ulsh et al. 2001). Also, the amount of blood obtained from such sites is very low and sometimes not enough for lymphocyte separation and culture.

We collected blood samples from the testudinids *Chelonoidis carbonaria* and *C. denticulata* and the chelids *Phrynops*

FIG. 1. A) Blood sampling from the marginal costal vein for *Chelonoidis carbonaria* (Testudinidae; inset enlarged to show the exact position). B) Blood sampling from the external jugular vein for *Phrynops geoffroanus* (Chelidae; inset enlarged to show the exact position).

geoffroanus and *P. hilarii* (10 adult animals for each species). The animals were from the "Reginaldo Uvo Leone" breeding farm in Tabapuã, São Paulo, Brazil (20.9965°S, 49.12128°W).

The sampling site was first cleaned with distilled water and 70% ethanol. For testudinids, the marginal costal vein, lateral to the longitudinal axis of the animal, was used as a blood sampling site. An insertion of 5 mm is necessary and should access close to the forelimb (Fig. 1A). Some adjustment in angle, insertion, and position of the needle may be necessary.

In chelids, the external jugular vein is relatively dorsal and superficial in the neck. The biventer cervical and transverse cervical muscles are good dorsal landmarks for the external jugular. These muscles are externally obvious and are to either side of the vessels; the external jugular is located deep and between them and medial to the transverse cervical muscle. Correct insertion of needle requires a 90° angle downward, right before the cranium base, and a 2 mm deep insertion is necessary (Fig. 1B). However, the correct access depends on the size of the animal. The syringe was withdrawn slowly to create a vacuum for easy sampling.

The marginal costal and external jugular veins are located in the peripheral part of the body, hence there is no chance of injury to vital organs and sufficient blood can easily be withdrawn from adult animals. Some adjustment in the needle size may be necessary for hatchlings. The volume of blood taken from a healthy animal should be no more than 1% of its weight (Fudge 2000).

After blood collection, the skin was again swabbed with 70% ethanol to prevent microbial infection and the turtles were left in plastic boxes for observation for four hours. None of the animals used in this study showed any ill effects related to blood sampling.

Our procedure on these species allows collecting enough blood for several studies. The methods demonstrated do not require anesthesia and can be adopted for several other turtles, facilitating the study of this important vertebrate group.

Acknowledgments.—We gratefully acknowledge Reginaldo Uvo Leone for letting us sample turtles on his farm. We are also grateful to Fundação de Amparo à Pesquisa do Estado de São Paulo (FAPESP - Grant number - 2009/0446-9, 2010/19785-0), Fundação para o Desenvolvimento da UNESP (FUNDUNESP - Grant number - 01098/07), and Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq) for financial support. The animal care procedures followed in this study were authorized by the Ethics Committee in Animal Experiments (ECAE) of the Faculdade de Medicina de São José do Rio Preto (FAMERP) (Protocol 5517/2008) and approved by IBAMA/SISBIO (2838725/ 16488-1 and 16488-2).

A Fully Adjustable Transmitter Belt for Ranids and Bufonids

Tracking free-ranging amphibians with radio telemetry yields invaluable data, but is difficult and laborious. Frogs and toads generally weigh <100 g, have thin, delicate skin without a protective covering, and a challenging body form for radio transmitter attachment. Because of these features, investigators must use small (<10 g) radio transmitters with limited range and battery life, and travel to the field on a regular basis to relocate each animal. For all this work and labor, the investigator needs a device that secures the radio transmitters to the animal without damaging its skin or otherwise harming it.

Transmitters can be either implanted (e.g., Carey 1978) or attached externally to anurans. Because external attachment generally has caused little or no effect on behavior or weight gain in anurans (Bartelt and Peterson 2000; Rowley and Alford 2007; Indermaur et al. 2008; Sullivan et al. 2008), and given the much less stress caused to the animal, it is the recommended approach for most study needs (Indermaur et al. 2008). A variety of attachment designs have been used to meet all the requirements of telemetry for anurans (e.g., beaded chains, Rathbun and Murphey 1996; 1 mm outside diameter plastic belts, Bartelt and Peterson 2000; nylon ribbons, P. Ritson and D. Pilliod, pers. comm.; see Bull 2000 for review). Some designs have worked better for certain species, study areas, or investigators. For example, plastic belts and nylon ribbons have worked well in some studies, but caused deep wounds on frogs and toads that we study in the Midwest; beaded chains, while working well for larger frogs, can be rather heavy for medium sized (20–30 g) frogs and their relatively widely spaced beads limits fine size adjustments; on toads, beaded chains tend to collect and hold dirt that then cuts into their rough, drier skin (F. Anderka, Holohil Systems, Ltd., pers. comm.). Other belts (e.g., Muths 2003; Rowley and Alford 2007) were designed for relatively short study periods (few weeks to a month) or included small beads that would seem to have a similar effect on toads as beaded chains. A "common" design (i.e., one that works well for both frogs and toads) could help simplify materials needed for telemetry. In addition, a belt that can be easily and finely adjusted to fit the animal as it grows throughout the season may help reduce the problem of skin sores. We developed a fully adjustable belt for our current study of Northern Leopard Frogs (*Lithobates pipiens*) and American Toads (*Anaxyrus americanus*). We describe its design and evaluate its performance over two seasons of study in north-central Iowa.

Methods.—We attached 1.8 g model BD-2 radio transmitters (Holohil Systems, Ltd., Carp, Ontario) to post-breeding adult frogs and toads during the 2009, 2010, and 2011 (current) field seasons. These radio transmitters have an expected battery life of 14 weeks and, based upon our field measurements, a typical detection range of 400–650 m. The waist belt was made from two sizes of flexible tubing and a length of thin (0.28 mm diameter), copper wire. Holohil Systems imbedded a 1 mm inside diameter (ID) plastic tube within the epoxy of the transmitter. The length of copper wire, approximately equal to the circumference of the animal's waist, was passed through this tube. Two lengths of dark gray, flexible PVC tubing (PVC 105–18, 1.0668 mm outside diameter (OD); Alphawire, Elizabeth, New Jersey), each equal to about one-third the animal's waist circumference, were slipped over the ends of the copper wire (one length on either side of the transmitter). We secured these lengths of PVC tubing against the transmitter by bending the ends of the copper wire over their ends (Fig. 1). The belt is secured around the animal's waist by passing the ends of the PVC tubing into a length of silicone tubing (1/16" ID and 1/8" OD; Cole Parmer Instrument Company, Vernon Hills, Illinois), cut to approximately one-half the circumference of the animal's waist (Fig. 2). The belt was adjusted for fit by changing the amount of PVC tubing extending inside the silicone tubing. Because the OD of the PVC tubing was very close to the ID of the silicone tubing, friction held the belt together (i.e., similar to a Chinese finger trap). The average (± SD) weight of twelve finished belts was 0.274 ± 0.041 g.

Results.—We used this belt on a total of 14 frogs and 20 toads during the 2009 and 2010 seasons, and seven frogs and 34 toads during the 2011 season. Making and attaching the belt required 5–10 minutes and the double-tube design made it easy to make fine adjustments in the field in less than one minute. During 2009–2010, frogs weighed an average (± SD) of 38.3 ± 11.0 g (range = 20–65 g); toads weighed an average of 34.6 ± 7.7 g (range = 22.5–55.5 g). The average length of time that frogs and toads wore the belt was 29 ± 24 and 34 ± 16 days, respectively. Factors limiting the time of telemetry with these animals included escaping the belt (~50%), predation (~20%), lost signal (~9%) and death (~9%) (Table 1). Six of the 20 toads and two of the 14 frogs developed minor skin abrasions that were easily and effectively treated in the field by applying Vitamin E to the sore and adjusting the belt; two additional toads developed more serious abrasions that required removal of the belt. Half (N = 8) of those animals that escaped did so after the long whip antenna became entangled in dense herbaceous vegetation. We eliminated this problem by shortening the whip antenna from a length of 15 cm to 10 cm.

During 2011, frogs weighed an average of 3.2 ± 8.7 g (range = 27–52 g); toads weighed an average of 35.9 ± 6.9 g (range = 22–52 g). Additional experience with this belt resulted in fewer lost animals and much longer tracking periods (Table 2). At the time of this writing (mid-July 2011), no animals have been lost due to antennas becoming entangled in herbaceous stems. We have released only one animal due to skin wounds and only four others have escaped the belt. Fates of others include predation (~32%), death (~20%), and lost signal (~7%).

Discussion.—This belt is light-weight (i.e., adds < 0.3 g to the radio transmitter), was easily attached and adjusted in the field

Table 1. Average weight, fate, and number of days tracked for Northern Leopard Frogs (NLF) and American Toads (AT) during 2009 and 2010 field seasons. Half of those that escaped did so when the antenna of their radio transmitters became entangled in dense vegetation; shortening the antenna eliminated this problem.

No. of NLF	Avg. Wt.	Fate	No. Days Tracked
3	36.0 ± 9.1	released	49.0 ± 13.8

3	37.3 ± 2.1	signal lost	34.7 ± 29.7

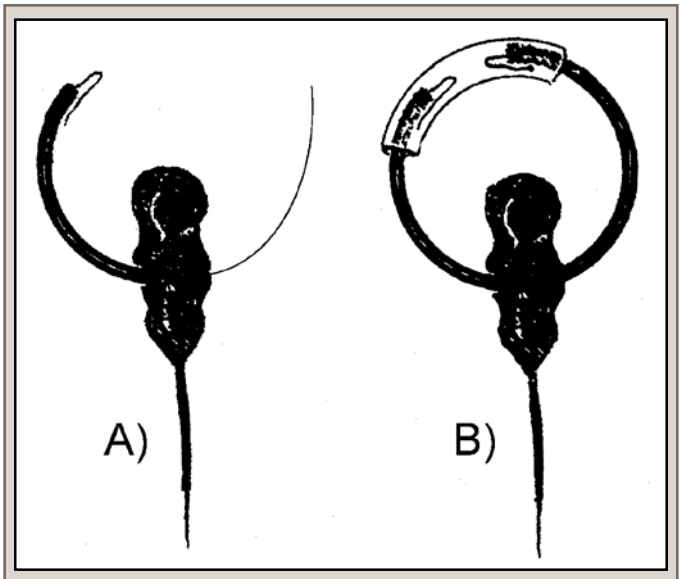

Fig. 1. Details of this belt design. A) Belt showing copper wire extending through one length of PVC tubing and 1 mm tube imbedded within the transmitter epoxy. The copper wire is bent over an end of the PVC tubing. B) Finished belt affixed to a radio transmitter. Both lengths of PVC tubing are held firmly against the transmitter by the copper wire. A length of silicone tubing fits snugly over each end of the PVC tubing and allows for easy and fine adjustments around the waist of a frog or toad. (A slight angle to this drawing makes the silicone tubing appear slightly off center.)

Fig. 2. Details of the belt attached to a Northern Leopard Frog. The length of silicone tubing, visible in the middle of the belt, makes the belt fully adjustable.

by one individual in under five minutes, seemed to be minimally invasive (affected normal behavior little and caused minimal injuries), and released the animal when it became entangled in dense vegetation. Two other attachment methods (a plastic belt, Bartelt and Peterson 2000, and a nylon ribbon, Pilliod and Ritson, pers. comm.) caused deep skin wounds on 19 of 30 animals. The smooth, rounded, larger diameter tubing of this belt distributed the point of contact over a larger area of the delicate skin. Its ease of attachment minimized the amount of time each animal was handled, lessening stress to the animal, and its ability to be finely adjusted throughout the season helps reduce skin sores.

The belt did not seem to interfere with normal, daily movements and behavior, or amplexus. Perhaps the biggest problem we encountered was when the long whip antenna became entangled in the dense growths of vegetation of restored prairies. The shortened antenna reduced the detection range of the radio signal by 50 m, or 10–15% of its previous detection range, but for this study the elimination of entangled antennas made this shortened range worthwhile. However, the shortened antenna may not be appropriate for tracking species that make longer distance movements, or use habitats that reduce detection ranges.

Belts with a feature that allows the radio transmitter to fall off the animal after many weeks helps ensure any animal whose signal is lost will not permanently carry the radio transmitter. We have recently discovered (2011) that the thin copper tends to

break after 9–12 weeks of wear in the field (= approx. battery life of the transmitter); we cannot yet claim this will happen consistently, but five have fallen off tracked toads (two radio transmitters were lying directly adjacent to the toads and reattached). If one needs to ensure the radio transmitter remains on an animal longer, a slightly thicker wire may be used, or the wire may be replaced with a continuous length of PVC tubing (the radio transmitter manufacturer will need to embed a tube with an ID of 1.1 mm). The weight of the 0.28 mm copper wire is approximately equal to the additional length of PVC tubing, so total transmitter weight would remain the same.

We tested this belt only on Northern Leopard Frogs and American Toads, but think it would be suitable for other medium to large species of ranids and bufonids for long-term (i.e. 3–5 month) studies. Like all other attachment methods, experience with this belt improved its success. We caution researchers to choose tubing colors that blend into the animals' natural habitats, check the animals frequently (e.g., once/week) for any sores or health problems, and to remove dead skin from the belt (dead skin clinging to belts seems to facilitate skin sores). This diligence can greatly diminish skin and health problems.

Acknowledgments.—We thank C. Lange, I. Bartelt, and A. March, and for their contribution of ideas and assistance in the field during this study. K. Carlson illustrated the belt and transmitter. R. Klaver provided helpful comments on an earlier draft of this manuscript. This study was funded by a U.S. Geological Survey grant to R. Klaver. This study satisfied all Animal Care guidelines of Waldorf College. Any mention of trade, product, or firm names is for descriptive purposes only, and does not imply endorsement by the U.S. Government.

Join us for the 7th World Congress of Herpetology
University of British Columbia, Vancouver, Canada
August 8-14, 2012

WCH-7 is open to all the world's herpetologists as well as their Ichthyologist colleagues.

Register **NOW** at http://wch2012vancouver.com

Society, committee and special interest meetings will kick off the event and exciting post congress tours will wrap up 5 full days of an eclectic and diverse scientific program.

WCH-7 will be an exceptional opportunity to meet and network with international colleagues in a stimulating and beautiful setting. Please join us in Vancouver this summer!

Call for Auction Items!

The SSAR/HL will be hosting a silent and live auction during WCH-7. Proceeds of the live auction will benefit the World Congress of Herpetology and donations of auction items are now being solicited! For details visit the WCH-7 website.

For further information, please visit our website: http://wch2012vancouver.com

Utilizing a Slide to Move Heavy-bodied Snakes

FIG. 1. Slide attached to exhibit with door open.

FIG. 2. Removing Gaboon Viper (*Bitis gabonica*) from exhibit with slide.

The manipulation of heavy-bodied snakes using traditional methods and tools can present difficulties for both the snake handler and the snake. The weight of a large animal feels substantially amplified at the end of a 36-inch (91.4 cm) snake hook and this increased weight can present a serious safety challenge with larger snakes.

For many heavy-bodied snakes that are primarily ground dwellers, being draped over a snake hook is very unnatural and will often result in excessive struggle leading to injury. In the process of manipulating these animals on traditional snake hooks, they commonly sustain rib fractures and less commonly spinal fractures (Altimari 1998). One technique to mitigate this challenge is to employ the use of two hooks to balance the weight

FIG. 3. Metal lip used to attach slide to steel track of exhibit.

FIG. 4. Gaboon Viper (*Bitis gabonica*) inside holding cooler after being moved on the slide, prior to lid being secured.

of the animal more evenly (Altimari 1998). In addition, the preferred hooks to use when manipulating various species of heavy-bodied snakes are more flattened, rather than round to further support the animal with minimal injury (Altimari 1998).

Another technique that is commonly used for the manipulation of heavy-bodied snakes is termed "tailing." This method involves the use of one snake hook and then restraining the snake by holding the tail with a hand. For our department it was decided not to utilize this type of manipulation in order to avoid any unnecessary risks inherent with this method of venomous snake handling.

The method utilized to move Gaboon Vipers (*Bitis gabonica*) in and out of exhibit space at the National Zoo involves a "slide" in conjunction with a snake hook (Fig.1). The slide supports the majority of the snake's weight during the move, with the snake hook used only for guidance and minimal manipulation (Fig. 2). The slide is constructed of pine plywood, sanded and varnished to prevent splintering. At the top of the slide a piece of angled sheet metal (1 in. × 7/8 in; 2.5 cm × 2.2 cm) was installed and bent to fit securely into an existing steel track attached directly under the exhibit door (Fig. 3). The slide is 42 in. (106.7 cm) long and wider at the top (20.5 in.; 52.1 cm) where it attaches to the steel tract and tapers more narrowly at the base (13.5 in.; 34.3 cm). Rails (3 in. W × 42 in. L; 7.6 cm × 106.7 cm) were installed on each side of the slide to prevent the animal from falling off the edge. In addition to the sheet metal lip locking into the track of the concrete wall the slide is supported by two legs measuring (2 in. W × 24 in. L; 5.1 cm × 61 cm) that fold for easy storage. A 24-gallon (91 liter) cooler is placed at the base of the slide as a holding container. An eye hook was attached to the lid of the cooler, which allows the lid to be properly secured with a snake hook while remaining out of the snake's striking range. The snake can easily be manipulated with a snake hook onto the slide and slowly guided downward into the container (Fig. 4). Once secured within the container, the exhibit is worked safely and the snake is returned to the exhibit using the slide yet again. This method of moving *B. gabonica* and other heavy-bodied species of snakes has been employed for many years at the National Zoo with no spinal injuries or other health problems for the snakes involved.

Acknowledgments.—We thank Béla Demeter for the concept and design of this piece of equipment. Photographs were taken by Mehgan Murphy, photographer, Smithsonian National Zoological Park.

HERPETOCULTURE NOTES

SQUAMATA — LIZARDS

LIOLAEMUS FORSTERI **(NCN). CANNIBALISM.** Cannibalism in lizards belonging to the genus *Liolaemus* has been reported previously (Rocha 1992. Herpetol. Rev. 23:60; Ripoll and Acosta 2007. Herpetol. Rev. 38:459, Kozykariski et al. 2009. Herpetol Rev. 40:89). This is the first report of cannibalistic behavior in *L. forsteri*, a species endemic to the higher elevations (4300–4900 m) of Bolivia (Baudoin and Pacheco 1991. *In* E. Forno and M. Baudoin [eds.], Historia Natural de un Valle en Los Andes, pp. 438–439. Instituto de Ecología, Universidad Mayor de San Andrés, La Paz).

On 9 August 2011 we observed a captive adult male *L. forsteri* (80 mm SVL) attack and eat a recently hatched individual of the same species (hatchlings have mean SVL = 34 ± 0.8 mm, N = 4). The attack occurred quite rapidly and concluded with the adult swallowing the whole body of the hatchling (Fig. 1). The adult male was evaluated using radiography 48 h after the event, but there was no visible evidence of the hatchling in the digestive track. However, fecal analysis confirmed the presence of skin remnants.

The species reported here as *L. forsteri* was considered as *L. signifer* until a recent taxonomic review (Aguilar-Kirigin 2011. Revisión Taxonómica y Sistemática del Género *Liolaemus* (Iguania:

PHOTOGRAPH TAKEN FROM VIDEO COURTESY OF MATÍAS BARCELÓ.

FIG. 1. Adult male *Liolaemus forsteri* swallowing a hatchling conspecific.

Liolaemidae) en el Altiplano y Valles Secos Interandinos del Departamento de La Paz-Bolivia. Licenciatura thesis. Univ. Mayor de San Andrés, La Paz. 106 pp.).

We thank Colección Bolivia de Fauna (CBF) and Dirección General de Biodiversidad of Bolivia for permits required to conduct this research. We also thank J. Salazar-Bravo and A. Aguilar-Kirigin for contributions on the manuscript.

***TROPIDURUS ITAMBERE*. ESCAPE BEHAVIOR.** Despite its wide distribution in Brazil (Rodrigues 1987. Arq. Zool. 31:105–230), there are few studies on the behavior of *Tropidurus itambere*. Escape behavior is expected to be under strong natural selection as predation is probably one of the most pervasive selective agents for most organisms. It is considered a secondary defense mechanism, and is used when errors occur in primary defense mechanisms (Edmunds 1974. Defense in Animals. Longman Group. New York. 357 pp.). Lizards can remain on their initial substrate type or escape to "preferred" substrates (Vanhooydonck and Damme. 2003. Funct. Ecol. 17:160–169.). Thus, specific locations and soils may increase an animal's chance of surviving a predatory attack (Vanhooydonck et al. 2007. Integr. Comp. Biol. 2007:1–11). Locomotor escape behavior is a defense mechanism widely used in lizards. Some species burrow into the substrate where they live or dive into sand (Greene 1988. *In* Gans and Huey [eds.], Biology of the Reptilia, pp. 1–50. Alan R. Liss, Inc., New York; Rocha 1993. Cienc. Cult. 45:116–122). To date, burial escape behavior in *T. itambere* has not been reported.

On 14 February 2010, we collected an adult male *T. itambere* (7.08 mm SVL) in Reserva Biológica Unilavras – Boqueirão (44.9172°W, 21.4011°S; 1250 m elev.), in a rocky field within Cerrado, in the municipality of Ingaí, state of Minas Gerais, Brazil. The behavior of this specimen was studied for 30 min. under laboratory conditions, using the focal animal method (Altmann 1974. Behaviour 49:227–267). The specimen was placed in a terrarium with sandy soil, with water, rocks, and natural vegetation obtained at the collection site. In the terrarium the lizard burrowed into the sand head first, using its forelimbs in fast, alternate movements of excavation. The lizard immediately curved its body into an "S" configuration and completed the burial using its hindlimbs, leaving only its head above the surface. In Cerrado areas, *T. itambere* is associated with rock fields (Rodrigues, *op. cit.*) and in Ingaí, these areas consist of rocky outcrops, usually in sandy soils (Pereira and Volpato 2005. Pro Hom. 4:27–34). *Tropidurus* is widely distributed geographically with both saxicolous and psammophilous forms, *T. itambere* being saxicolous (Faria and Araújo 2004. Braz. J. Biol. 64:775–786). It may be that burial escape behavior is an ancestral trait within *Tropidurus* that has been retained in the genus as speciation occurred across different substrate types.

The current study reports burial behavior exhibited by *T. itambere* from Brazil for the first time. The specimen (CRLZ 000178) was deposited at the Coleção de Répteis do Laboratório de Zoologia, Centro Universitário de Lavras - UNILAVRAS, municipality of Lavras, Minas Gerais, Brazil.

This work was licensed by IBAMA (Process nº 14740-2). We thank Fabiano M. Vieria (UFRRJ) for suggestions in preparing the manuscript.

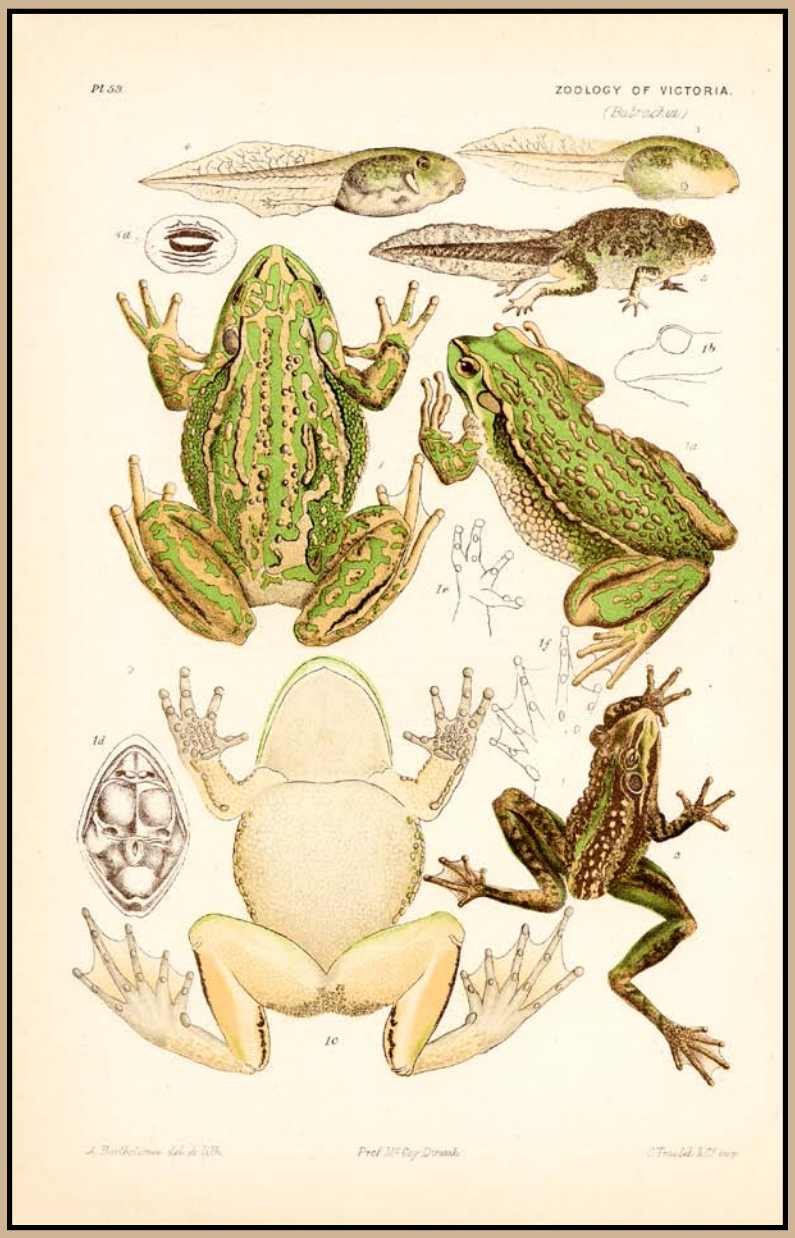
SQUAMATA — SNAKES

***BOGERTOPHIS SUBOCULARIS* (Trans-Pecos Ratsnake). UNUSUAL BEHAVIOR DURING FEEDING.** On 14 November 2006, I observed a long-term captive adult male *Bogertophis subocularis* exhibiting an interesting tail movement behavior herein termed "pre-prandial caudal flicking." I have observed this behavior multiple times over the past five years in both wild caught and captive bred individuals of this species and in a captive bred *Pantherophis bairdi* (Baird's Ratsnake).

In each case, laboratory mice (*Mus musculus*) were offered as live prey or previously euthanized (frozen and thawed). All mice were placed behind cage furniture (e.g., a section of cork bark), which obstructed the view of the snakes to the prey item. It was apparent by the snakes' behavior (alertness, repeated tongue flicks and searching) that they were fully aware of the proximity of the prey item. After approximately 10 seconds of searching behavior, each snake would remain nearly motionless but rigid with only the tail moving. The movement of the tail is best described as intermittent bouts of rapid, spontaneous flailing in a wide-ranging motion. Each burst of movement was characterized by a thrashing or whipping action of the tail lasting approximately 2 seconds with periods of no movement lasting 4–6 seconds. As soon as the mice were located they were quickly seized and constricted.



The type of movement described most resembled the frantic caudal trembling exhibited by many eublepharid geckos just before a predatory strike directed towards an invertebrate prey item (Kaverkin 2005. *In* A. Kirschner, H. Seufer, and Y. Kaverkin [eds.], Eyelash Geckos: Care, Breeding and Natural History, pp. 127–132. Kirschner & Seufer Verlag, Karlsruhe). However, it differed from

this behavior in that all caudal movement ceased when the prey objects were visually located by the snakes. The observed behavior is very different from the caudal luring behaviors described for New World pit vipers, (Sazima 1991. Copeia 1991:245–248) and the Green Tree Python (*Morelia viridis*; Murphy et al. 1976. J. Herpetol. 12:117–119; Maxwell 2003. The Complete Chondro: A Comprehensive Guide to the Care and Breeding of the Green Tree Python. ECO Herpetological Publishing, Lansing, Michigan. 247 pp.) where the tip of the tail is raised and moved in a slower "inch worm"-like motion. This is also vastly different from the tail buzzing or vibrating behavior that many species of snakes, including *B. subocularis*, use as a defensive, warning behavior when threatened by a predator (Rhoads 2008. The Complete Suboc: A Comprehensive Guide to the Natural History, Care, and Breeding of the Trans-Pecos Ratsnake. ECO Herpetological Publishing, Lansing, Michigan. 291 pp.).

I thank Jack W. Sites and James B. Murphy for help with this note.

ART IN HERPETOLOGY

The illustration at left originally accompanied an article titled: "Ranoidea aurea, The Green and Golden Bell-Frog," *published in 1881 within the pages of Prodromus of the Zoology of Victoria; or Figures and Descriptions of the Living Species of All Classes of the Victorian Indigenous Animals*. This periodical, published in twenty parts from 1878 to 1890 by the National Museum of Melbourne was met with critical acclaim and wide popular support. John McCoy (1823–1899), director of the National Museum of Melbourne, wrote the text and employed a number of artists to illustrate his work, including Arthur Bartholomew, the illustrator and lithographer of this piece. Bartholomew was born in Bruton, Somerset Shire, England in 1834. In 1852, at 18 years of age, he left his homeland and moved to Australia. Not long after his arrival in Melbourne, he set forth to explore the Australian bush and ventured to Tasmania where he met his wife, with whom he had two children.

Bartholomew returned to Melbourne with his family where, in 1859, he was appointed Attendant in Melbourne University's department of Natural History. It was here he met McCoy, who recognized Bartholomew's artistic abilities. McCoy hired Bartholomew to complete a series of zoological and geological illustrations for several projects, including the *Prodromus*. Bartholomew was known to illustrate living specimens, which included several frog species that he tended to keep in the laboratory adjacent to McCoy's lecture room. A characteristic of Bartholomew's work is the use of line drawings within his illustrations to provide diagnostic features of each species. Examples of these line drawings can be seen in this piece. This is the first illustration showing the natural colors of the species, now known as *Litoria aurea*.

Bartholomew's career as a biological illustrator spanned 40 years, a period of time that would see him illustrate over 700 zoological specimens and an as-yet undocumented number of geological and paleontological specimens. He died in Melbourne in 1909. Additional information can be found at http://museumvictoria.com.au/caughtandcoloured/.

Chytrid Fungus, *Batrachochytrium dendrobatidis* (*Bd*), Detected at Lower Elevations in Puerto Rico: Implications for Conservation of Puerto Rican Crested Toad (*Peltophryne lemur*)

The Puerto Rican Crested Toad, *Peltophryne lemur*, is federally listed as Threatened (U.S. Fish and Wildlife Service 1992) and Critically Endangered by the International Union for Conservation of Nature and Natural Resources (IUCN 2011). It is the only native toad of Puerto Rico and is a representative of an ancient and distinctive clade of Bufonidae that is distinguished from other species by its unique elongated snout and pronounced cranial crest (Pramuk 2006; Pramuk et al. 2007). Once widespread throughout the karst regions, the last remaining wild population has been reduced to a small area within the southwestern part of the island and fluctuates between 300 and 3,000 individuals (M. Canals, unpubl. data).

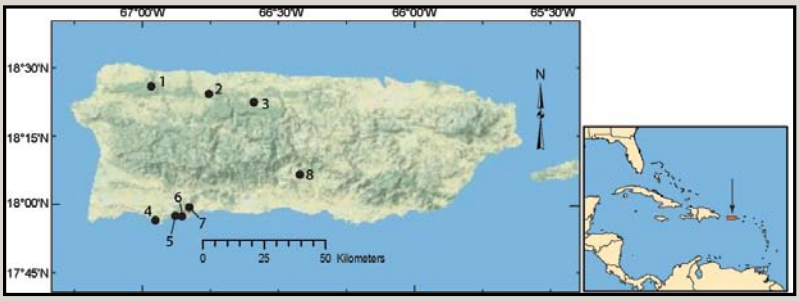

FIG. 1. Map of Puerto Rico. Numbers correspond to the following collection sites: Quebradillas (1), Arecibo (El Tallonal) (2), Rio Encantado (3), Manglillo (4), Aroma (5), Tamarindo (6), Ventana (7), Coamo (Gabia) (8).

Recovery efforts for this species include a reintroduction program directed by the United States Fish and Wildlife Service (USFWS), the Puerto Rican Department of Natural and Environmental Resources (PRDNER), and the Association of Zoos and Aquariums Puerto Rican Crested Toad Species Survival Plan (PRCT SSP). Since intensive reintroduction began in 1992, more than 179,000 tadpoles produced from captive-bred toads held primarily in North American zoos have been released onto the island. These efforts have resulted in the establishment of three new breeding populations. In recent years, monitoring efforts have increased at all current known toad localities, as well as historic and potential reintroduction sites. Random sampling for the chytrid fungus, *Batrachochytrium dendrobatidis* (*Bd*), began in 2006 (Table 1) in order to assess the overall health of the wild *P. lemur* populations and mitigate threats that might be introduced via disease from other amphibian species.

The earliest record of chytridiomycosis detected in Puerto Rico was from preserved *Eleutherodactylus* specimens collected in 1976 (Burrowes et al. 2008). *Bd* has been reported from 7 of 15 localities surveyed within the island, all of which were found at elevations above 600 m (Burrowes et al. 2008). Herein, I report the detection of *Bd* at two additional sites within Puerto Rico at lower elevations than previously reported (Table 1). These recent findings are important to consider relative to future *in situ* and *ex situ* conservation management strategies developed for *P. lemur*.

Random samples were taken of live amphibian species opportunistically while visiting known *P. lemur* sites and one potential new reintroduction site from 2006 to 2011 (Fig. 1). All *P. lemur* samples were taken from wild specimens (not recently metamorphosed from a reintroduction program). Juvenile and adult anurans were captured by hand. Latex gloves were worn and changed between each sampling event. Standard preventative measures were taken while processing specimens to prevent the risk of disease transmission and sample contamination. The ventral skin surface of each anuran was swabbed 25 times around the forelimbs, stomach, pelvic region, legs and toes using a sterile cotton swab. Each sample was stored in an individual vial containing 70% ethanol until processed. All samples were processed at Pisces Molecular LLC (Boulder, Colorado, USA) using a Polymerase Chain Reaction assay method developed by Seanna Annis, which was modified for greater specificity and sensitivity. A total of 157 samples were processed representing seven species at eight sites.

All samples were negative, with the exception of two samples rated as "strongly positive" by Pisces. *Bd* was confirmed from an *Eleutherodactylus antillensis* collected in 2010 from a potential new release site for *P. lemur* in Rio Encantado at an elevation of approximately 192 m. The second *Bd*-positive sample was collected from an *Eleuthrodactylus coqui* at a current reintroduction site in Arecibo at an elevation of close to 82 m (Table 1).

Bd has been attributed to the possible extinction of at least three species of coqui (*Eleutherodactylus karlschmidti, E. jasperi*, and *E. eneidae*) in Puerto Rico (Longo and Burrowes 2010). It is unknown if *Bd* has contributed to the decline of *P. lemur*, or if it will affect populations in the future. The last known wild population inhabits dry, scrub forest, which might be too inhospitable for the pathogen due to high diurnal temperatures and lack of moisture. However, reintroduced *P. lemur* populations now exist in historic areas of karst habitat within moist rainforests, which are more favorable conditions for *Bd* persistence (Lips et al. 2008; Woodhams et al. 2008). Preliminary studies of skin peptides in a small sample of captive *P. lemur* suggest that they do not possess peptides with antimicrobial activity (J. D. King, pers. comm. 2009). Although these peptides often are present in species of amphibians that exhibit a natural immunity to *Bd* (Rollins-Smith et al. 2003; Rollins-Smith and Colon 2005), not all species secrete them (Conlon et al. 2009; Conlon 2011). Therefore, the susceptibility of *P. lemur* to an outbreak of *Bd* remains unknown. Studies are currently underway using non-genetically essential captive *P. lemur* to determine if this species can tolerate exposure to *Bd*. These findings have bearing on future reintroduction efforts and management decisions for wild populations of *P. lemur* within Puerto Rico.

Acknowledgments.—I thank all of the volunteers who have helped acquire samples during my visits and the Association of Zoos and Aquariums facilities that participate in the PRCT SSP program. A special thanks is extended to all of our partners and friends in Puerto Rico, especially Carlos Pacheco, Jan Paul Zegarra, Miguel Canals, Juan Casanova, Fernando Bird, Alberto Puentes, Jorge Ortiz, and

Abel Vale, who continuously support and contribute to the conservation efforts for the Sapo Concho Puertorriqueño. I am grateful to the Buffalo, Detroit, North Carolina, Sedgwick County, and Toronto Zoos for funding this health assessment portion of the crested toad field project and to the Fort Worth Zoo for continuous support. As always, generous logistical support was provided by the Caribbean USFWS Field Office, PRDNER, The Conservation Trust of Puerto Rico and Citizens of the Karst to gain access to collection sites. Permission for this work was granted through PRDNER and USFWS Endangered Species Permit #TE121400-4 and all applicable institutional animal care guidelines were followed.

Current State of *Bd* Occurrence in the Czech Republic

Chytridiomycosis, a relatively new amphibian disease caused by the chytrid fungus *Batrachochytrium dendrobatidis* (*Bd*) (Berger et al. 1998; Longcore et al. 1999), is recognized as a global threat to amphibian biodiversity. The presence of *Bd* has had the worst impact on amphibia in Australia and the Neotropics. Other areas with intensive research and *Bd*-mediated population declines are North America and Western Europe. To date, Eastern Europe and Asia are among those areas with the least research in relation to *Bd* (Fisher et al. 2009).

The first results of broadscale *Bd* detection from Central Europe are just emerging (Ohst et al. 2011; Sztatecsny and Glaser 2011). According to these findings, *Bd* seems to be broadly distributed and quite unspecific in the hosts it infects. Although Central Europe is home to many amphibian species potentially susceptible to the disease, no adverse impact on populations or *Bd*-mediated deaths have been observed so far. Considering *Bd*'s recent emergence, we still have limited information as to its impact on species and populations here. In the Czech Republic, only negative results from limited sample sets were available until 2007 (Garner et al. 2005; Ouellet et al. 2005). Herein, we present recent results of *Bd* sampling done in the Czech Republic.

In 2010, a systematic large-scale sampling design was implemented among the diverse regions of the Czech Republic. *Bd* samples were collected primarily during spring and summer months by skin swabbing of live amphibians. This is a nondestructive method used by most chytridiomycosis researchers in the world (Hyatt et al. 2007). At each locality, we endeavored to reach a minimum of 30 samples per species/life stage in order to be able objectively assess *Bd* occurrence (Garner in litt. 2008). Individuals were captured by hand wearing disposable gloves or by dip net. All prescribed hygienic precautionary measures were taken (Wellington and Haering 2008). Sampled individuals were photographed and returned to their place of capture. In the case of dead individuals found, the last two toes from one leg were collected and preserved in 95% ethanol for future analysis. *Bd* detections were made using Taqman real time qPCR (Boyle et al. 2004), in part at the Institute of Zoology (Zoological Society of London) and in part at the Department of Biology and Wildlife Diseases (University of Veterinary and Pharmaceutical Sciences Brno, Czech Republic).

We detected *Bd* in 41 of 466 (9%) animals sampled overall, in 4 of 10 species sampled, and at 8 of 11 sites sampled (Table 1). In 2008, *Bd* was detected for the first time in the Czech Republic in the Common Toad, *Bufo bufo*, and water frogs of the genus *Pelophylax* (Baláž et al. 2009). In 2010, we found *Bd* in the

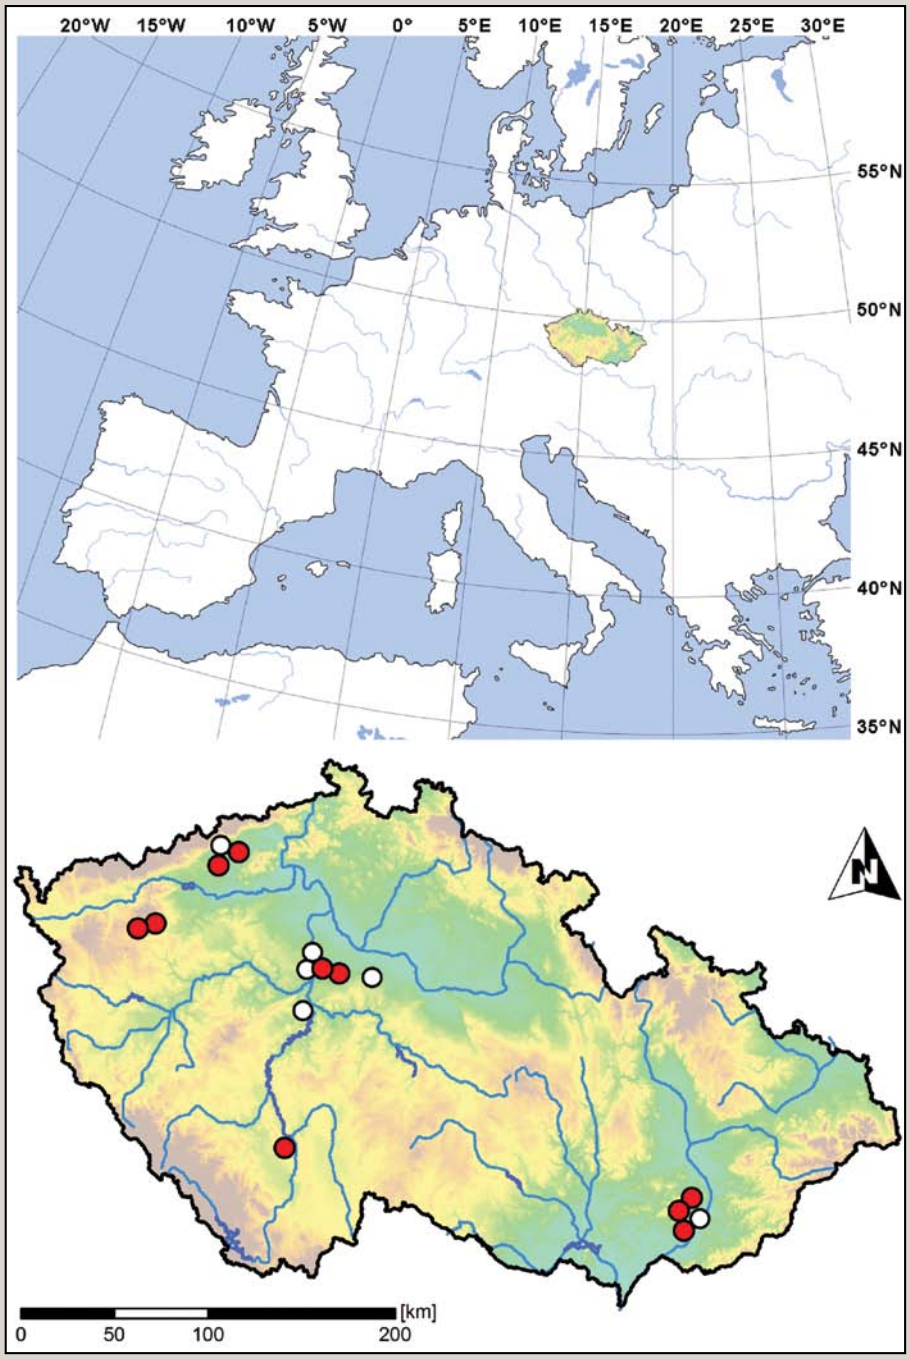

FIG. 1. Locations of amphibian populations in the Czech Republic that tested positive for *Batrachochytrium dendrobatidis* (red circles) and localities where all samples were negative (white circles). These data include the current study and unpublished data using the same methods from another six localities sampled during 2008–2009 (Vörös et al., unpubl.).

European Fire-bellied Toad, *Bombina bombina,* and the Yellow-bellied Toad, *B. variegata,* in eight discrete localities (Fig. 1, Table 1). *Bd* was most prevalent in the genus *Bombina,* however our results show very low GE values (genomic equivalent of 1 *Bd* zoospore). The observed prevalence might be underestimated because the PCR reaction that we used contained neither an internal positive control (IPC) (Hyatt et al. 2007) nor BSA (bovine serum albumin) for reduction of reaction inhibition (Garland et al. 2010). However, very similar prevalence data were already published from both Luxembourg (Wood et al. 2009) and Germany (Ohst et al. 2011), which support our observations. Several positive samples had GE values close to the detection limit of the method and only a few reached a magnitude of 10^1, but their fluorescence increase curves showed no problems with the qPCR reaction. Therefore, our results likely show low prevalence and low intensity of infection in the specimens carrying the pathogen. This is also supported by the fact that although all sampled individuals were photographed in detail, no visual symptoms of chytridiomycosis were found in *Bd*-positive animals. All dead and suspicious specimens (lethargic, abnormal sitting posture, fearless, half-closed eyes, etc.) sampled were *Bd*-negative.

In Europe to date, *Bd* has been found in more than one-third (29) of Europe's amphibian species in 13 countries (Austria, the Czech Republic, Denmark, France, Germany, Great Britain, Hungary, Italy, Luxembourg, Poland, Portugal, Spain, Switzerland) (Ohst et al. 2011; Sztatecsny and Glaser 2011; Civiš et al. 2010; Sura et al. 2010; Baláž et al. 2009; Wood et al. 2009; Garner et al. 2005; Vörös et al. unpubl.). These *Bd*-positive taxa include 19 of 21 species living in the Czech Republic.

Results from Austria (Sztatecsny and Glaser 2011), Germany (Ohst et al. 2011), Poland (Sura et al. 2010), and the Czech Republic (this paper) support the occurrence of *Bd* across Central Europe. However, the intensity of research is still notably lagging here relative to Western Europe. Thus, the data gathered to date do not allow for assessing the potential risks to Czech amphibians and their populations, which are in many cases already small and are in decline for other reasons unrelated to this disease. In the Czech Republic, therefore, at least essential precautionary steps via hygiene protocols could be established to address the disease, including approaches to mitigate its potential spread to new areas or species. Since 2010, we are conducting a more comprehensive sample, which should aid this assessment for the development of science-supported potential future management directions.

Survey of Ranavirus and the Fungus *Batrachochytrium dendrobatidis* in Frogs of Central Virginia, USA

The Global Amphibian Assessment found that 42% of amphibian populations are in decline, and 32% of species globally face extinction in the near future (IUCN 2008). Emerging infectious diseases, including the fungus *Batrachochytrium dendrobatidis* (*Bd*) and ranaviruses, have been responsible for mass die-offs and are considered major international threats (Daszak et al. 1999; Schloegel et al. 2010). Ranavirus has low host specificity; fish, reptiles and amphibians can be lethally or asymptomatically infected and can serve as reservoirs for other vulnerable species (Chinchar 2002; Schock et al. 2008). Surveillance of these pathogens is important for understanding their distribution and potential threat to amphibians and other animals. We used non-destructive sampling to survey for *Bd* and ranavirus in central Virginia, USA. No amphibian die-offs had been recorded in this area, although dedicated monitoring had not previously occurred.

On eleven trips from 1 April through 2 July 2010 we swabbed adult animals and collected toe clips to assess the presence of *Bd* and ranavirus, respectively, in four anuran species in three water bodies in Prince Edward County, Virginia: Briery Creek Lake in Briery Creek Wildlife Management Area (north end of the lake; 37.2005°N, 78.4497°W), and two ponds on the campus of Hampden-Sydney College (Chalgrove: 37.2428°N, 78.4639°W and Tadpole Hole; 37.2452°N, 78.4529°W). Chalgrove and Tadpole Hole are both approximately 1 ha and located 0.8 km apart. Briery Creek Lake is a 342-ha lake located 4.5 km south of the other ponds. We collected adult frogs by hand, typically between 1900–2300 h. Each frog was placed in a new plastic bag, and nitrile gloves were changed between catching individuals. While processing animals, we used a recommended protocol with two people to prevent contamination of samples (Brem et al. 2007). To sample for *Bd*, frogs were swabbed five times with sterile cotton-tipped applicators on both sides of the abdomen, ventral abdomen, ventral surface of thighs, and rear feet (Brem et al. 2007). To sample for ranavirus, the front-right toes of large species (*Lithobates catesbeianus, L. palustris, Anaxyrus fowleri*) or 1–2 hind-right toes of small frogs (*Pseudacris crucifer, Acris crepitans*) were collected using sterile surgical blades (St-Amour and Lesbarrères 2007). Both swab tips and tissue samples were preserved in 70% ethanol. All animals were released within 1–3 h at the original site of capture. To prevent cross-contamination between sites, all supplies and equipment were disinfected with 1% Nolvasan. Although Nolvalsan has not been tested against *Bd*, it is used as a fungicide, bactericide, and virucide, has

RACHEL M. GOODMAN*

**Corresponding author; e-mail: rgoodman@hsc.edu*

been proven to inactivate ranavirus at levels that are not toxic to amphibians, and is less caustic to equipment than bleach (Bryan et al. 2009; Kennedy et al. 2000). All materials that directly contacted animals (gloves, bags, scalpel blades, swabs) were used only once and contacted no more than one individual.

Of the 140 frogs processed, 103 were tested for ranavirus and *Bd*. Only species within a site that had ≥14 individuals were tested, because of the likelihood of misclassifying as uninfected sites with small sample sizes and low prevalence (Greer and Collins 2007). Disease testing was performed by the Veterinary Diagnostic and Investigational Laboratory in the College of Veterinary Medicine at University of Georgia. In brief, genomic DNA was extracted from toes following the tissue method of a commercially available kit (DNeasy Blood and Tissue Kit, Qiagen Inc., Valencia, California, USA). Conventional PCR was then performed using the protocol and primer sets reported by Annis et al. (2004) for Bd and those found in Mao et al. (1996, 1997; primers MCP4 and MCP5) for ranavirus. The PCR products were resolved via electrophoresis on a 1.0% agarose gel. Controls for all PCR runs included two negative controls (water and tissue from a ranavirus-negative tadpole) and two positive controls (cultured ranavirus and tissue from an experimentally infected and confirmed ranavirus-positive tadpole). The PCR reactions were repeated once to confirm results.

Bd was found in three of the five species tested, and at each of the three water bodies (Table 1). Among species with positives in a site, prevalence of the pathogen ranged from 6–20% (Table 1). No obvious pathological signs or dead or moribund animals were observed during the course of this study.

While ranavirus has been detected in a number of amphibian species sampled in the southeastern United States, including species in the current study: Bullfrogs (*Lithobates catesbeianus*), Cricket Frogs (*Acris crepitans*), Pickerel Frogs (*L. palustris*), Spring Peepers (*Pseudacris crucifer*), and Wood Frogs (*L. sylvaticus*) (Gray et al. 2009), none of the toe clips from the 103 frogs screened tested positive for ranavirus. Ranavirus was, however, detected in syntopic aquatic turtles, with prevalence ranging from 5–31.6% at these three sites, in a companion study using similar sample sizes and distal tissues (Goodman et al., unpubl.), which raises the question of whether we missed infections in the anuran populations.

We are confident that we did not miss infections in the animals we screened. St-Amour and Lesbarrères (2007) found that toe tips were comparable to liver tissue samples in detecting ranavirus in Green Frogs (*L. clamitans*), and although Greer and Collins (2007) demonstrated that tail clips were less sensitive than pulverized whole body samples in detecting ranavirus in salamanders, this difference disappeared after the first week post exposure. Our sample sizes were small within species at each site. However, combining species yields samples of 34 individuals at Briery, 33 at Chalgrove, and 36 at Tadpole Hole, which are sample sizes that should (with 95% confidence) be able to detect ranavirus prevalence of 10% or greater in a site (Brem et al. 2007). Importantly, we did not sample all species in each site, nor did we sample all life stages for any species. Thus if ranavirus was present, it was at likely at low prevalence, in an alternate life stage, or in another host species. Expanded monitoring is needed to establish whether ranavirus infects frogs at these sites.

Bd occurred with low prevalence in *P. crucifer*, *L. palustris*, and *A. crepitans*, but was not detected in *L. catesbeianus* or *A. fowleri* (each collected in one site). Larger sample sizes would be needed to rule out the possibility of infection in these species, especially

TABLE 1. Prevalence (number positive/number tested) and associated 95% confidence intervals (CI) for *Batrachochytrium dendrobatidis* (*Bd*) occurrence in frogs from three water bodies in central Virginia. Dashes indicate that small sample sizes precluded tested for that species and location. The 95% confidence intervals with no continuity correction were calculated using a program by Lowry (2011) based on methods in Newcombe (1998) and Wilson (1927).

because of the low prevalence of the pathogen estimated for co-occurring species. *Lithobates catesbeianus* has been shown to carry *Bd* but experience low morbidity and mortality due to infection (Daszak et al. 2004) and so it is surprising that infections were not detected. *Anaxyrus* species are also susceptible to *Bd*, though some studies have found absence or low prevalence in sites where other species tested positive (Rothermel et al. 2008; Tupper et al. 2011; Venesky et al. 2011). The current study adds to a body of research showing presence of the fungus *Bd* in frog populations that are seemingly asymptomatic. However, dedicated surveillance would be necessary to determine the potential impacts of *Bd* on local amphibian health and fitness.

Acknowledgments.— We are grateful to Hampden-Sydney College, the Biology Department, and the Honors Program for providing funding and support for this research. All work in this study was approved by the Hampden-Sydney College Animal Care and Use Committee and performed under scientific collection permit 38354 from Virginia Department of Game & Inland Fisheries. We thank Briery Creek Wildlife Management for permitting us to work on the site, Debra Miller and Lisa Whittington for conducting laboratory tests at the University of Georgia, Matthew Gray for assistance in setting up this surveillance project, and Zach Harrelson, Allen Luck, Sam Smith, and Erica Rutherford for assistance in the field. Debra Miller also provided many helpful comments on this manuscript.

Batrachochytrium dendrobatidis Detected in Fowler's Toad (*Anaxyrus fowleri*) Populations in Memphis, Tennessee, USA

In North America, amphibian declines due to *Batrachochytrium dendrobatidis* (*Bd*) infection have primarily been documented in the western U.S. (Bradley et al. 2002; Fellers et al. 2001; Muths et al. 2003), yet *Bd* infections also have been detected in several southeastern U.S. states (e.g., www.Bd-maps.net; Green and Dodd 2007; Rothermel et al. 2008), including Tennessee (Chatfield et al. 2009). *Bd* has been detected in rural Shelby County, north of Memphis, Tennessee, USA (Venesky and Brem 2008). However, *Bd* infection prevalence in urban and suburban Memphis has not been evaluated, but may be important since the city is located on the Mississippi River and notably, is transected east-to-west by two tributaries of the Mississippi River, the Wolf River and Nonconnah Creek (Fig. 1), and by numerous small urban tributaries including ditches, storm drains, and creeks. Aquatic corridors likely serve as connectivity pathways for amphibians, and hence may also serve to transmit *Bd*. The goals of our study were to determine *Bd* infection prevalence in Fowler's toads (*Anaxyrus fowleri*; formerly *Bufo fowleri*) at several Memphis locations and examine *Bd* prevalence among locations relative to proximity to major nearby waterways, which may serve as toad dispersal corridors.

We sampled for *Bd* from 11 *A. fowleri* populations located across the Memphis metropolitan area (Fig. 1) in 2009 by opportunistically collecting individual toads by hand during walking surveys adjacent to ponds and lakes. We collected 10–24 adults (males and females) from each site and also 12 post-metamorphic juveniles of unknown sex from 5 of the 11 sites (Table 1). Adult animals were sampled during the breeding season (April–June) whereas juvenile animals were sampled following metamorphosis (June–August). Fresh nitrile gloves were used when handling each toad to prevent cross-contamination of samples and we used a sterile fine-tipped swab (Catalog #MW113, Advantage Bundling / Medical Wire Co., Durham, North Carolina, USA) to swab the abdomen, pelvic patch, ventral hind limbs, and hind feet of each toad. Swabs were individually placed into a sterile 5-ml vial (model #985744, Wheaton Science Products, Millville, New Jersey, USA) and stored in darkness at 25°C until sent to the San Diego Zoo Amphibian Disease Laboratory for analysis using real-time (Taqman) qPCR as described by Boyle et al. (2004). We calculated the percentage and 95% binomial confidence interval of both *Bd*-positive adult toads and study sites with *Bd*-positive toads.

We used a handheld GPS unit (model 60CsX, Garmin International, Inc., Olathe, Kansas, USA) to record the coordinates of the approximate center of each sampling site (Table 1). We used ArcGIS (ESRI version 9.3, Redlands, California, USA) to map the location of each sampling site and to add a circular buffer around each site to identify the potential for *A. fowleri* to access major waterways that could allow greater dispersal distances (Fig. 1). The buffer has a radius of 624 m, which is twice the maximum reported movement distance of *A. fowleri* (312 m; Clarke 1974), but is a reasonable estimate of greater possible movement distances in *A. fowleri* that are comparable to the similar-sized congeners *A. americanus* (Oldham 1966) and *A. boreas* (Muths 2003). We also measured the distance (m) from each sampling site to the nearest river and used a Student's t-test ($\alpha = 0.05$) to determine whether sampling sites with *Bd*-positive individuals were located closer to rivers than sites without *Bd*-positive individuals.

Eleven of 159 (6.9%; 3.9–12%) adult *A. fowleri* at 8 of 11 (72.7%; 43.4–90.2%) sites were *Bd*-positive, yet none of the 60 juveniles sampled were infected (Table 1). Notably, there were no more than two *Bd*-infected toads at any site and the qPCR Ct (Cycle threshold) values (Table 1) indicated that *Bd* infection intensities were relatively low (mean = 37.5; 95% confidence interval = 35.0–40.1). Ct values reflect the number of cycles required to amplify the *Bd* DNA to a detectable level, thus the lower the Ct value the more *Bd* DNA was initially present. Five of eight (62.5%) sites with *Bd*-positive individuals were located within 624 m of a river, yet all three sites without *Bd*-positive individuals were beyond this distance limit (Fig. 1). Despite this, *Bd*-positive and *Bd*-negative sites did not differ ($t = -1.22$, d.f. = 4.85, $P = 0.28$) in mean distance (m) to the nearest river.

Bd was present in the majority of *A. fowleri* populations sampled, however *Bd* infection was not widespread among individuals sampled from each population and was found only in adult toads (Table 1; Fig. 1). Non-detection of *Bd* in three adult populations and in all juvenile *A. fowleri* sampled must be interpreted cautiously because our sample size was low (Skerratt et al. 2008), however high *Bd*-infection prevalence can be detected with sample sizes similar to ours (e.g., McCracken et al. 2009; Zellmer et al. 2008). Moreover, *Bd* was confirmed in adult toads at four of five juvenile sampling sites (Table 1) so the potential for juvenile toads to have been infected exists, yet additional studies are needed to identify possible reasons why no juvenile *A. fowleri* in this study were infected with *Bd*. Transmission of *Bd* among individuals within each site may have been limited because *Bd*-infected toads in this study appeared to have relatively low intensity infections (depending on the efficiency of the system, qPCR Ct values > 35 are typically indicative of single digit copies of DNA; Heid et al. 1996; Table 1) and none presented clinical signs of chytridiomycosis. Other wild amphibians including *Lithobates catesbeianus*, *Litoria wilcoxii*, and *Taudactylus eungellensis*, have been shown to appear asymptomatic, yet carry light *Bd* infections (Hanselmann et al. 2004; Retallick et al. 2004). These results suggest that *A. fowleri* may mount effective immune responses to *Bd* or demonstrate seasonal variation in *Bd* infection incidence or intensity as shown in other species

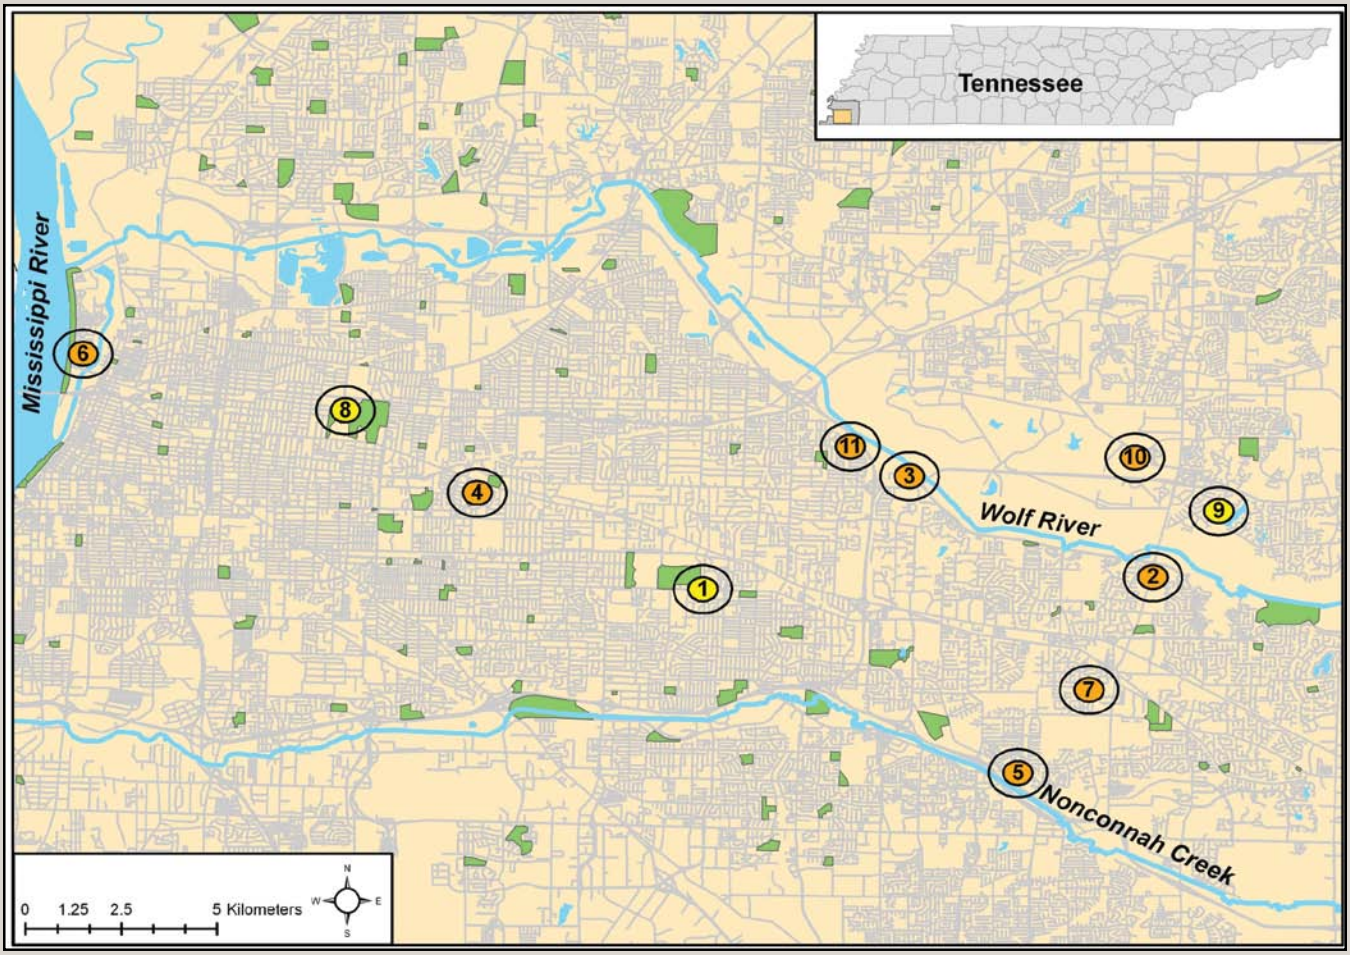

FIG. 1. Locations (N = 11) in Memphis, Tennessee, USA where adult and post-metamorphic juvenile *Anaxyrus fowleri* were sampled for *Batrachochytrium dendrobatidis* (*Bd*). *Bd*-positive adult toads were detected at eight sampling sites (orange fill) and we failed to detect *Bd* at three sites (yellow fill). The number within the circle indicates the sampling site (Table 1) and the circle around each site number represents a 624-m buffer, which was used to identify likely access to rivers that may be possible toad dispersal routes. Note that 5 of 8 sites with *Bd*-positive toads were within 624 m of a possible toad dispersal route.

TABLE 1. Results of *Batrachochytrium dendrobatidis* (*Bd*) sampling in adult and post-metamorphic juvenile *Anaxyrus fowleri* in Memphis, Tennesseee, USA. qPCR Ct values indicate *Bd* infection intensity, with a lower Ct value indicating a higher *Bd* level.

(Berger et al. 2004; Gaertner et al. 2009; Kriger and Hero 2006a, b; Richmond et al. 2009). Either mechanism would enable *A. fowleri* to be a *Bd* reservoir from which *Bd* infection could be transmitted to the local amphibian community. In order to elucidate the host-pathogen dynamics and environmental influences on *Bd* pathogenesis, further research including long-term mark-recapture studies to assess survivorship may be warranted for seemingly resistant species like *A. fowleri*.

The distance to the nearest river from most of the sampling sites with *Bd*-positive toads was less than 624 m, whereas all 3 sites without *Bd*-positive toads were > 624 m from these possible amphibian dispersal routes (Fig. 1). However, sites with and without *Bd*-positive toads did not differ significantly in mean distance (m) to the nearest river in this study. This may be attributable to a low sample size since retrospective power analysis indicated that 28

sampling sites would be required to determine whether distance to the nearest major river differs between sites with and without *Bd*-positive toads. Moreover, we did not survey small tributaries, ditches, storm drains, etc. that can support *A. fowleri* and provide potentially more continuous connectivity among locations. Regardless, adult *A. fowleri* can move up to 312 m (Clarke 1974) and we conservatively suggest that these toads are capable of traversing twice that distance since similar-sized congeners can do so (Oldham 1966; Muths 2003). Other sympatric amphibians at our study sites including *Pseudacris crucifer* (Delzell 1958) have maximum dispersal differences that are similar (573 m) to *A. fowleri*, and moreover *Lithobates pipiens* (Seburn et al. 1997) and *L. catesbeianus* (Ingram and Raney 1943) both have much greater dispersal distances (> 1 km), which make these species potentially important to long-distance transmission of *Bd*. Thus, further study is needed to understand the spatial epidemiology of chytridiomycosis and specifically, the potential for amphibians like *A. fowleri* to be *Bd* reservoirs whose movements may establish continuous connections between source populations (e.g., those at ponds and lakes) and rivers that may allow dispersal of *Bd*-infected amphibians.

The data presented herein contribute to our understanding of *Bd* spatial distribution and host ecology by documenting that *Bd* is present in Memphis, Tennessee, infection prevalence and intensity are relatively low in *A. fowleri*, and *Bd* infection status is unrelated to the distance to the nearest river (Table 1; Fig. 1). Additional studies are needed because the spatial epidemiology of chytridiomycosis and species-specific reactions to *Bd* infection are not well known, yet are vital to our understanding of possible treatment interventions for 'at risk' populations.

Acknowledgments.—This research was supported by a Memphis Zoo Conservation Action Network grant (JD and CV) and the Memphis Zoo Biodiversity Internship Program (DE). We especially thank the San Diego Zoo Amphibian Disease Laboratory for qPCR analysis of samples, S. Boyle (Rhodes College) for GIS assistance, and T. Boozalis, S. Cassel, N. Davis, A. Graham, and L. Lieb for field assistance. This study was conducted in accordance with the Institutional Animal Care and Use Committee (IACUC) of the Memphis Zoo (# 2008-06) and Rhodes College (# 099) under Tennessee Wildlife Resources Agency Scientific Collecting Permit # 3506.

First Record of *Batrachochytrium dendrobatidis* in *Physalaemus fernandezae* (Anura: Leiuperidae) for Buenos Aires Province, Argentina

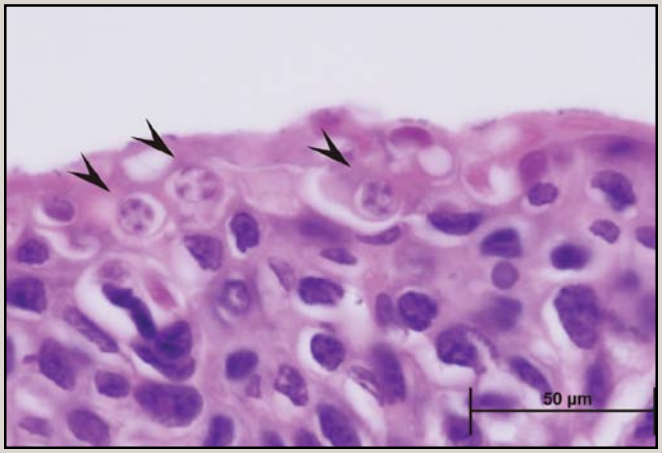

FIG. 1. Histologic section of ventral epidermis of an adult specimen of *Physalaemus fernandezae* from Punta Lara Natural Reserve, Buenos Aires province, Argentina. Arrows indicate the presence of zoosporangia of *Batrachochytrium dendrobatidis* with zoospores.

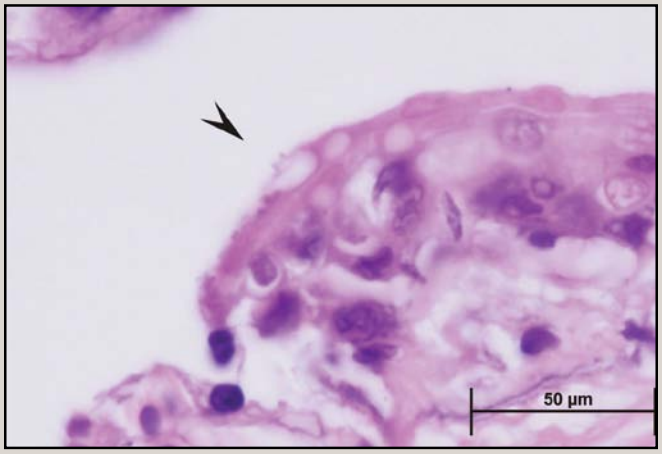

FIG. 2. Histologic section of ventral epidermis of an adult specimen of *Physalaemus fernandezae* from Punta Lara Natural Reserve, Buenos Aires province, Argentina. The arrow indicates an empty zoosporangium, with discharge tube.

In Argentina, *Batrachochytrium dendrobatidis* (*Bd*) is known from Buenos Aires, Córdoba, Misiones, Neuquén, San Luis, Salta, and Tucumán provinces (Arellano et al. 2009; Barrionuevo and Mangione 2006; Fox et al. 2006; Ghirardi et al. 2009; Gutierrez et al. 2010; Herrera et al. 2005). We provide the first record of *Bd* infection in a population of the pond-breeding anuran *Physalaemus fernandezae*, from Punta Lara Natural Reserve (34.8033˚S, 58.0099˚W), Ensenada, Buenos Aires province, Argentina.

Punta Lara Natural Reserve is located on the western bank of Río de La Plata. It has a warm-temperate climate with a mean annual temperature of 16˚C (-4˚C minimum; 42˚C maximum), and has a few days with frost, mostly in June and July. Annual precipitation is slightly over 1000 mm (SMN 2011).

Physalaemus fernandezae is distributed in Buenos Aires and Entre Ríos provinces, Argentina, and some localities from southern Uruguay (Barrio 1964). It reproduces mainly in marshy grasslands with two reproductive events per year (Barrio, *op. cit.*). The dominant breeding season takes places between May and August (colder temperature months), but may extend until December, in many cases overlapping reproductive events with others sympatric anurans: e.g., *Hypsiboas pulchellus*, *Odontophrynus americanus*, and *Scinax squalirostris*. The second reproductive event involves fewer animals and takes place approximately between February to March, coinciding with reproduction activities of *Dendrosophus nanus*, *D. sanborni*, *Hypsiboas pulchellus*, *Pseudopaludicola falcipes*, *Pseudis minuta*, *Scinax squalirostris*, *S. berthae*, and *S. granulatus*. Currently, *P. fernandezae* has an IUCN conservation status of Minor Concern (IUCN 2011).

Seven adult specimens of *P. fernandezae* were collected at Punta Lara Natural Reserve in September 2007, preserved in 10% formalin and deposited in the herpetological collection of Museo de La Plata (MLP-A 5385–5391). A skin sample (length: 5 mm; width: 2 mm) was taken from the ventral zone of selected specimens, immersed in paraffin, thin-sectioned every 5 µm with a microtome (Leica, RM 2125 RT), mounted onto a microscopic slide and stained with haematoxilin and eosin, after Drury and Wallington (1980). Histological slides were analyzed for *Bd* following procedures described in Berger et al. (1999), with a binocular microscope (Olympus Optical Co. Ltd., Tokyo, Japan; model BX 50). Diagnostic images were taken with an Olympus DP 71 digital camera mounted to the scope.

The presence of *Bd* was confirmed for 3 of 7 (42.85%) skin samples analyzed. Different developmental stages of chytridiomycosis were clearly visible, namely: zoosporangia (isolated and grouped), empty and containing zoospores (Fig. 1), diagnostic

characteristics such as a septum and discharge tube (Fig. 2), and hyperplasic epidermis.

It is worth mentioning that the population of *P. fernandezae* used in this study has been studied by local herpetologists since 2001, but no moribund or dead specimens have been recorded to date. Moreover, the individuals on which infection was detected had been engaged in reproductive activities.

Acknowledgments.—We are grateful to Josefina V. Candioti and Marcelo L. Larramendy for use of their microscope and digital camera. We thank Allan P. Pessier for his critical review of the photos.

Low Prevalence of *Batrachochytrium dendrobatidis* in Two Plethodontid Salamanders from North Carolina, USA

Although the pathogenic fungus *Batrachochytrium dendrobatidis* (*Bd*) was first isolated from anuran amphibians, subsequent research has clearly shown that it also infects many species of caudate amphibians. Opportunistic sampling surveys have shown that at least 56 species of salamanders from the families Ambystomatidae, Amphiumidae, Salamandridae, Cryptobranchidae, and Plethodontidae in the United States harbor *Bd* (reviewed in Bryne et al. 2008; Olson 2010). The effect of *Bd* on salamander demography, however, is less understood than its impact on anuran populations. Laboratory challenge experiments have shown that salamanders can be infected by *Bd* and show mortality from chytridiomycosis (Chinnadurai et al. 2009; Vazquez et al. 2009; Weinstein 2009), but more sampling and monitoring of salamanders will help elucidate potential ecological and/or climatic variables that may influence the susceptibility of salamanders in the wild. Here, we contribute information on the prevalence and distribution of *Bd* in salamander populations by testing 166 individuals from two localities in North Carolina, USA. Our results expand upon previous reports of *Bd* infection in amphibian populations in North Carolina (e.g., Bryne et al. 2009; Keitzer et al. 2011; Rothermel et al. 2008).

We opportunistically sampled two plethodontid salamander species at two collection sites on 8–12 August 2010 (Fig. 1). At Deep Gap, we collected salamanders by turning over rocks and logs that were located up to 15 m from a stream. The collecting site at Wayah Bald was a grassy area near the forest edge. We swabbed each salamander 30 times using sterile swabs (Medical wire No. 113) in the manner of Boyle et al. (2004) and Kriger et al. (2006). Each animal was handled with a clean pair of latex gloves. No animals showed any outward signs of disease. After swabbing, animals were retained for additional studies under permits issued by the North Carolina Wildlife Resources Commission and the U.S. Forest Service to LDH. Swabs were stored in 100% ethanol and transported to Cornell University, where molecular testing was performed by Kiemnec-Tyburczy.

Genomic DNA was extracted from the swabs using Prepman Ultra following the protocol of Boyle et al. (2004). The level of *Bd* zoospore load was assessed using the method of Boyle et al. (2004). Briefly, this method used Taqman quantitative PCR to determine the total number of *Bd* zoospore genome equivalents in each unknown sample, based on known standards that were run simultaneously. To maximize cost efficiency but retain individual information, PCRs were run in singlicates at 1:10

dilutions. Studies have shown that there is no statistical difference in sensitivity or specificity between the singlicate and triplicate assays (Kriger et al. 2006). Every swab sample was run with (1) two negative controls, (2) an internal positive control (ABI Cat. No. 4308323) to test for potential inhibition and contamination, and (3) a range of *Bd* standards corresponding to 0.1, 1, 10, and 100 and 1000 zoospore DNA equivalents in duplicate (Hyatt et al. 2007). Samples that were positive for *Bd* in the first round of qPCR were re-run to confirm loads using the same template dilution. We categorized an individual as *Bd*-positive if its swab sample had ≥ 1 zoospore equivalent in both runs (Boyle et al. 2004). We calculated a mean prevalence (and 95% confidence interval) for each site using Clopper-Pearson binomial confidence intervals (Clopper and Pearson 1934).

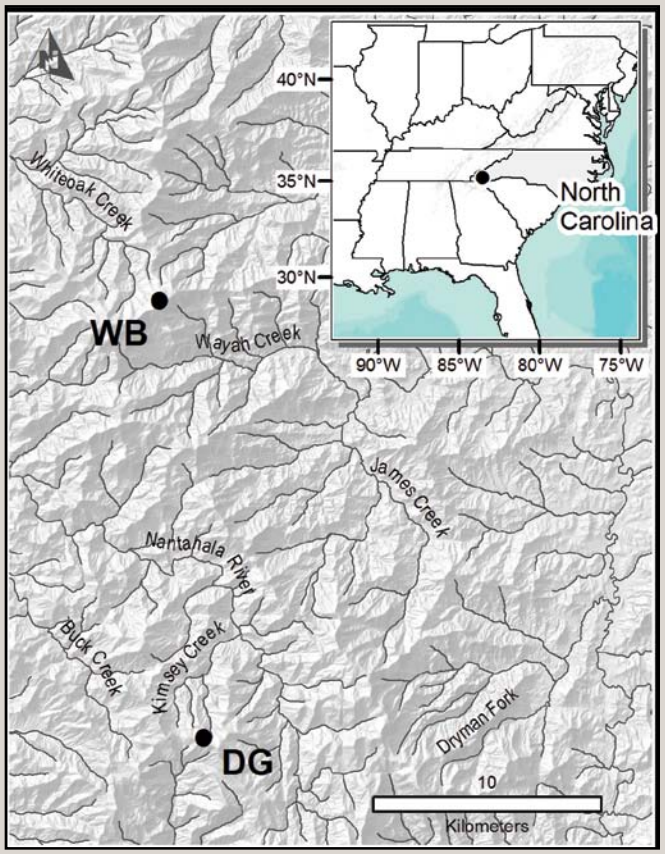

FIG 1. Specific location and topography of two sites in North Carolina, USA (inset; shaded state), where salamanders were tested for the presence of *Batrachochytrium dendrobatidis* (*Bd*). DG = Deep Gap, WB = Wayah Bald.

TABLE 1. *Batrachochytrium dendrobatidis* (*Bd*) prevalence (number of *Bd*-positive animals/total sampled) in plethodontid salamanders in North Carolina, USA.

Locality	Species	Prevalence ♀	♂	Juvenile	Total
Deep Gap (35.0389°N, 83.5431°W)	*Desmognathus ocoee*	1/23	1/31	2/16	4/70
	Plethodon shermani	1/11	0/6	0/13	1/30
Wayah Bald (35.1803°N, 83.5606°W)	*Desmognathus ocoee*	0/1	0/0	0/0	0/1
	Plethodon shermani	1/26	2/14	1/25	4/65

We found that 9 of 166 (5.4%) animals tested positive for *Bd*. Both species—*Desmognathus ocoee* and *Plethodon shermani*—had *Bd*-positive individuals (Table 1). *Plethodon shermani* is a direct-developing species that is commonly found under leaf litter, logs, and rocks. In contrast, *D. ocoee* has an aquatic larval stage and often is associated with seepages and streams (and thus may be more likely to come in contact with *Bd* zoospores). Despite these differences in life histories, both species had similar *Bd* prevalence levels. To our knowledge, this is the first published report of *Bd* infecting these two species, although Keitzer et al. (2011) tested one *P. shermani* and 53 *D. ocoee* at Coweeta Hydrologic Laboratory (Macon Co., North Carolina) but did not detect *Bd* on any individuals. We note, however, that our sampling occurred slightly later in the year and may have occurred at higher elevations. The elevation of our two localities, Deep Gap and Wayah Bald—approximately 1300 m and 1630 m, respectively—are in the upper end of the elevation range of the Coweeta area that was sampled (675–1592 m), and thus our localities may have been cooler and perhaps more suitable for *Bd*.

The prevalence of *Bd* at Deep Gap was 0.050 (95% CI: 0.016–0.11), whereas the prevalence at Wayah Bald was slightly higher at 0.061 (95% CI: 0.017–0.15). All of the zoospore loads we quantified were very low. The highest load we calculated was 57 zoospores, and most of the positive samples contained 3–4 zoospores (range 1–57 zoospores). We did not observe any trend towards particular life stages or sexes being infected within the two species (Table 1), although the animal with the highest load was a juvenile *P. shermani* from Wayah Bald. The low levels of prevalence, combined the lack of clinical signs of disease, suggests that *Bd* exists primarily as a subclinical infection in *D. ocoee* at Deep Gap and in *P. shermani* at Wayah Bald, at least during the summer months.

Our data are consistent with other studies of plethodontid populations that have shown that *Bd* prevalence in some populations is relatively low, but that *Bd* is present in North Carolina (e.g., Keitzer et al. 2011; Rothermel et al. 2008). *Bd* also has been found in other species of *Plethodon* and *Desmognathus* in other areas of the USA. Prevalence in *P. glutinosus* and *P. yonahlossee* in Watauga County, North Carolina was 1/40 and 1/41, respectively (Chinnadurai et al. 2009). *Desmognathus conanti* (Timpe et al. 2008) and *D. fuscus* (Grant et al. 2008) have also tested positive for *Bd*. In fact, *Bd* has been found on plethodontid species as diverse as *Pseudotriton ruber* (Montanucci 2009), *Batrachoseps attenuatus* (Weinstein 2009), *Bolitoglossa dofleini* (Pasmans et al. 2004) and *Plethodon neomexicanus* (Cummer et al. 2005). In other salamander families, population surveys have reported varying estimates of prevalence. A survey of *Notophthalmus viridescens* found 16 of 63 individuals infected in localities in Georgia, North Carolina, and Virginia (Rothermel et al. 2008), whereas another found prevalence in *N. viridescens* varied between 0–100% across multiple ponds in Pennsylvania (Groner and Relyea 2010). Prevalence in ambystomatid salamanders also varies widely; Ouellet et al. (2005) found 4/139 *Ambystoma maculatum* infected across Canada while Padgett-Flohr and Longcore (2005) found 2/11 *A. californiense* infected in two ponds. These studies highlight the need for further work investigating how disease-related mortality has impacted natural populations historically. Further testing across multiple seasons and years is necessary to better understand *Bd* infection dynamics in salamanders.

Acknowledgments.—We thank Corina Wack, Kari Leichty and Damien Wilburn for assistance with swab collection; Ana Longo for help with qPCR protocol optimization; and David Rodriguez and Kelly Christiansen for creating the locality figure. The protocols were approved by the Cornell University Institutional Animal Care and Use Committee. This study was funded by a National Science Foundation grant to KMK and LDH (IOS-0808589).

Detection of *Batrachochytrium dendrobatidis* in Amphibian Populations of Northeast Ohio

The first North American occurrence of *Batrachochytrium dendrobatidis* (*Bd*) was documented in Quebec in 1961 (Ouellet et al. 2005). As of 2009, *Bd* had been detected in five Canadian provinces and at least 38 US states (for example, Hossack et al. 2010; Sadinski et al. 2010; Fisher et al. 2009; Slough 2009; Muths et al. 2008; Rothermel et al. 2008; Adams et al. 2007; Longcore et al. 2007; Steiner and Lehtinen 2007; Ouellet et al. 2005, and many others, see www.Bd-maps.net). In Ohio, *Bd* has been detected via PCR analysis in wild Northern Leopard Frogs (*Lithobates pipiens*), American Toads (*Anaxyrus americanus*) (Scott and Sheafor, unpubl.), and Blanchard's Cricket Frogs (*Acris blanchardi*) (Steiner and Lehtinen 2008). In addition, Fowler's Toads (*Anaxyrus fowleri*) and cricket frogs captured in Ohio and held at the Toledo Zoo were later found to be infected with *Bd* (G. Lipps, pers. comm.). It is uncertain, however, whether these animals were infected prior to arriving at the zoo, or if they contracted it from other infected species already present at the zoo. Histological surveys of Fowler's Toad museum specimens originally collected from Ashtabula County, Ohio in 1977 determined that the samples were *Bd*-positive (Scott and Sheafor, unpubl.), indicating that *Bd* has been in the northeastern Ohio region for at least three decades. Because *Bd* has been detected in field-collected amphibians from northeast Ohio, the possibility exists that the

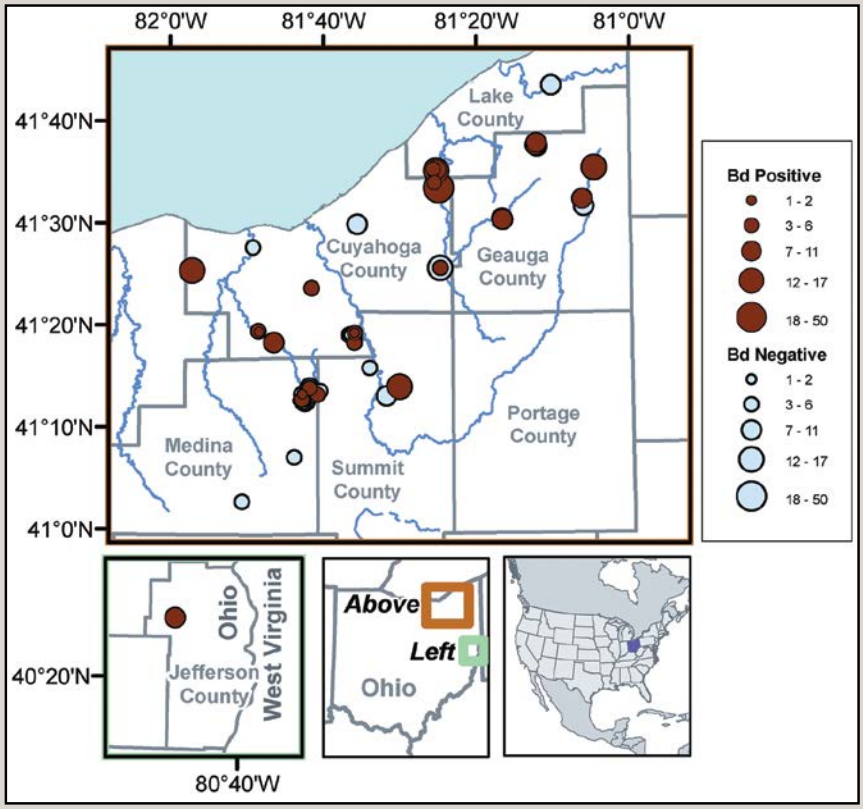

FIG. 1. *Batrachochytrium dendrobatidis* (*Bd*) sampling locations in Northeastern Ohio with both positive and negative sites in the five counties sampled. Circle size indicates sample size.

TABLE 1. Amphibian species sampled for *Batrachochytrium dendrobatidis* (*Bd*) in northeast Ohio, USA.

Species	No. Sampled	No. Positive (%)
Ambystoma jeffersonianum	32	12 (37.5)
Ambystoma maculatum	31	9 (29)
Ambystoma opacum	5	0
Anaxyrus americanus	24	5 (20.8)
Desmognathus fuscus	31	1 (3.2)
Desmognathus ochrophaeus	22	3 (13.6)
Eurycea bislineata	59	4 (6.8)
Eurycea longicauda	5	0
Pseudacris crucifer	15	4 (26.7)
Notophthalmus viridescens	16	8 (50)
Plethodon cinereus	61	10 (16.4)
Plethodon glutinosus	8	0
Pseudotriton ruber	16	3 (18.7)
Lithobates catesbeianus	8	4 (50)
Lithobates clamitans	54	5 (9.2)
Lithobates pipiens	1	0
Lithobates palustris	5	3 (60)
Lithobates sylvaticus	38	16 (41)
Total	431	87 (20.2)

current amphibian population may be descended from survivors of a previous, unrecorded population decline that occurred sometime after initial introduction of *Bd* to the area (Daszak et al. 1999). The purpose of our survey was to determine presence and geographic distribution of *Bd* in a portion of northeastern Ohio.

Sampling occurred in 2007 and 2008, from mid-March to October at a total of 68 sites in six Ohio counties (Cuyahoga, Geauga, Jefferson, Lake, Medina, and Summit). Volunteers, students, and staff from Cleveland State University, John Carroll University, Cleveland Metroparks, Geauga Park District, and Medina County Park District participated in the project. Most (56/72) sites were classified as forested (> 60% canopy cover), with 12 woodland (< 60% canopy cover), and four open sites. Streams were visited most frequently with 33 perennial and six intermittent streams sampled during the year. Fourteen vernal pools and eight permanent or temporary lakes and ponds were sampled across the region. Wet forests, marshes, and unclassified forests made up the remainder of the sites. Medina County streams were sampled heavily (23 streams) because one team is engaged in a headwater stream assessment project in Cleveland Metroparks Hinckley Reservation.

Two-person (minimum) crews followed an established swab-sampling protocol for collection and preservation of samples (Brem et al. 2007; Livo 2004). Extensive sampling occurred from March to May in forested vernal pools and semi-permanent ponds in woodlands and open areas across northeast Ohio. From mid-May through October, several sites were re-sampled, and additional sampling occurred in stream and riparian areas in Cuyahoga Valley National Park and Hinckley Reservation of Cleveland Metroparks. Amphibians were captured by hand, or with dip nets or minnow traps. When multiple individuals were captured in minnow traps no more than 5 individuals of each species was sampled to decrease pseudo-replication and limit the total number of samples obtained. All equipment and personal gear was disinfected with 10% bleach solution between sites. For each amphibian captured, a clean dip net was used, which was disinfected after use.

All swab samples were placed into individual, labeled microcentrifuge vials containing 70% ethanol. The vials were deposited at the University of Mount Union, Alliance, Ohio for qPCR assay. Microcentrifuge vials containing swabs in 70% ethanol were vortexed for 45 sec and then centrifuged for 3 min at 16,000 × g in an Eppendorf model 5415 microcentrifuge (Eppendorf North America, Hauppauge, New York). After removing the swab, each vial was centrifuged again and the supernatant was carefully removed by aspiration. Prepman Ultra™ (Applied Biosystems, Carlsbad, California) (50 µL) was added and the vial was vortexed for 20 sec to mix the contents. Samples were incubated for 10 min on a boiling water bath, cooled to room temperature, and then centrifuged as above. An aliquot of the supernatant from each sample was diluted 10× with distilled water and used for qPCR.

Quantitative PCR was performed on an MJ Mini thermocycler with a Mini Opticon Real-Time PCR system (Bio-Rad Laboratories, Inc., Hercules, California), according to the method employed by Kirshtein et al. (2007). The 25-µL reaction mixture consisted of 12.5 µL iQ™ SYBR Green Supermix (Bio Rad), 1.2 µM each of primers ITS1-3Chytr and 5.8Schytr, and 5 µL of DNA sample. After one 15 min Taq activation step at 94°C, 40 cycles of 95°C for 30 sec, 57°C, for 30 sec, and 70°C for 30 sec were performed. Melting curves were conducted at the end of each reaction to check for the appearance of primer dimers. Periodic verification of the 146 bp amplified fragment was carried out by electrophoresis on 1.5% agarose gels. Zoospore extracts were prepared from a *Bd* strain isolated from the skin of an infected Northern Leopard Frog found in the Oak Openings Metropark near Toledo, Ohio and maintained on 1% tryptone in our laboratory since 2006. A standard curve, expressed as genome equivalents (*ge*), was prepared from a dilution series of zoospore extracts of known concentration. Positive results were indicated when greater than 0.1 genome equivalent was detected in the qPCR sample.

In total, 431 amphibians were sampled, representing 18 species (8 anuran and 10 caudate) (Table 1). Green Frogs (*Lithobates clamitans*), Red-backed Salamanders (*Plethodon cinereus*), and Northern Two-lined Salamanders (*Eurycea bislineata*) comprised nearly 40% of the samples. Species frequency at any particular site was primarily a function of where field crews were operating and not necessarily an indication of species abundance. Eighty-seven (87) animals tested positive for *Bd* (20.2%), including 14 of 18 species sampled. Wood Frogs (*Lithobates sylvaticus*), Red-backed Salamanders, and Jefferson Salamanders (*Ambystoma jeffersonianum* complex) exhibited the three highest numbers of positive results; however, Pickerel Frogs (*Lithobates palustris*), American Bullfrogs (*Lithobates catesbeianus*), and Northern Spring Peepers (*Pseudacris crucifer*) comprised at least 50% of individuals testing positive for *Bd*; however for those four species testing negative, sample size was very small (N < 8).

Detection of *Bd* was geographically widespread and present in all six counties sampled (Fig. 1), with 37.5% (27/72) of sites containing at least one individual testing positive. Those sites testing negative may be a result of low sample size at a given site (min N = 1, max N = 16).

Our survey represents the largest known effort to document the presence of *Bd* in Ohio. The results confirm the presence of *Bd* in 14 amphibian species (6 anuran and 8 caudate), and *Bd* appears to be geographically widespread, with the lack of detection likely resulting from a low sample size or effort in a given location. With the majority of sampling conducted during March through May, we expected to document *Bd* in explosive-breeding species concentrated in vernal pools where infection can be easily transmitted. We did not expect to document such a large number of positive results in the more terrestrial Red-back Salamanders. These results support the possibility that the amphibian community in Ohio is composed of post-*Bd*-infection populations. Long-term effects of the documented widespread *Bd* infections are still unknown.

Acknowledgments.—We thank Cleveland Metroparks, Mount Union College, and Cleveland Zoological Society for providing funding for this project, as well as Geauga, Lake, Medina, and Cleveland Metroparks for providing staff and volunteers to assist in sampling.

Occurrence of the Fungal Pathogen *Batrachochytrium dendrobatidis* among Eastern Hellbender Populations (*Cryptobranchus a. alleganiensis*) within the Allegheny-Ohio and Susquehanna River Drainages, Pennsylvania, USA

In North America, *Batrachochytrium dendrobatidis* (*Bd*) has been detected among numerous anuran and salamander species in the northwest (Pearl et al. 2007), west (Muths et al. 2003), southeast (Grant et al. 2008; Rothermel et al 2008), northeast (Longcore et al. 2007), and Canada (Ouellet et al. 2005) (see also www.Bd-maps.net). Efforts to describe the taxonomic and geographic extent of *Bd* occurrence are comparatively limited in Pennsylvania. Three studies, examining two ranid, two hylid, two plethodontid, and one salamandrid species, detected the presence of *Bd* on two species, the Red-spotted Newt (*Notophthalmus viridescens*) in central and northwestern Pennsylvania and the Green Frog (*Lithobates clamitans*) in the northwestern region of the state (Glenney et al. 2010; Groner and Relyea 2010; Raffel et al. 2010). Representatives of families Bufonidae, Pelobatidae, Ambystomatidae, Proteidae, and Cryptobranchidae have not been tested for *Bd* in Pennsylvania.

The Hellbender Salamander (*Cryptobranchus alleganiensis*) is a cryptic, stream-dwelling cryptobranchid that has received considerable attention with regard to its population status and conservation needs (Briggler et al. 2007). During the past five decades, numerous researchers have noted changes in the distribution and size of hellbender populations throughout its range in the mid-western and eastern United States (Philips and Humphries 2005). Quantitative evidence of population declines has been reported for the Ozark Hellbender (*Cryptobranchus a. bishopi*) and Eastern Hellbender (*Cryptobranchus a. alleganiensis*) in Arkansas and Missouri (Trauth et al. 1992; Wheeler et al. 2003) and for *C. a. alleganiensis* in the upper Allegheny drainage of New York (Foster et al. 2009). Factors associated with declines include habitat modification and loss, introduced species, and exploitation by humans (Briggler et al. 2007). The disease ecology of hellbenders is poorly studied, although *Bd* has been detected in multiple populations of *C. a. bishopi* and *C. a. alleganiensis* in Missouri and Arkansas and among individual *C. a. alleganiensis* in one Georgia stream (Briggler et al. 2008; Gonynor et al. 2011). Our goal was to assess the occurrence of *Bd* among multiple populations of *C. a. alleganiensis* within the two largest river drainages in Pennsylvania.

During June–August 2009–2010, we assessed *Bd* occurrence among populations of hellbenders associated with four streams within the north-central region of the Susquehanna River drainage and four streams within the Allegheny-Ohio River drainage (Fig. 1). Hellbenders were typically located and captured under large flat rocks and then placed in a plastic tote or mesh laundry bag during processing to obtain *Bd* samples. To minimize cross-contamination, disease sampling was performed while wearing new latex or nitrile gloves for each hellbender. Using a sterile cotton-tipped applicator cut to 2.5 cm length, we swabbed the ventral surface of the feet (fives times each), dorsolateral folds (five times each), and cloaca (five times) of each salamander. We used the cut end of the applicator to gently scrape dorsolateral folds (five times each) of each salamander and then immediately placed the swab in a labeled, 2 mL screw-cap vial containing 1 mL of 70% ethanol. For all hellbenders captured and swabbed, we measured individual total length (cm) and mass (g), qualitatively assessed each salamander for evidence of morbidity, and then released each salamander where it had been captured. Hellbenders ranging from 13–30 cm TL were assigned to the juvenile age class unless secondary sexual characteristics were evident. To minimize potential transfer of *Bd* among sites, all field equipment was treated with a 10% bleach solution, washed with warm water, and then allowed to dry for 24 h before reuse (Johnson et al. 2003). Storage totes and mesh bags were used to hold only a single hellbender on any given field day and then treated as described for other field equipment.

With the exception of hellbenders at one stream, our study populations had not been assessed for *Bd* so we chose to pool swabs for site-level assays of *Bd* occurrence. We split individual swabs into lengthwise halves in sterile laboratory conditions, saved one half-swab in the original screw-cap vial, and pooled the other half-swab with similarly prepared swabs collected from the same population. During pooling, half-swabs were placed in 15 mL screw-cap vials containing 70% ethanol (4–8 half-swabs = 1 pooled sample). In 2008, one hellbender from Loyalsock Creek was confirmed as *Bd*-infected so swabs collected from salamanders at this site were individually assayed. Pooled and individual samples were assayed for the presence of the *Bd* ribosomal RNA Intervening Transcribed Sequence (ITS) region by 45 cycle single-round PCR amplification. All *Bd* assays were performed by Pisces Molecular LLC, Boulder, Colorado.

We swabbed 59 juvenile and adult hellbenders collected from six streams during 2009 (Tubmill/Hendricks Creek, Little Mahoning Creek, Loyalsock Creek, Lycoming Creek, Little Pine Creek, and Kettle Creek) and 19 juvenile and adult hellbenders from two additional streams during our 2010 field season (Oil

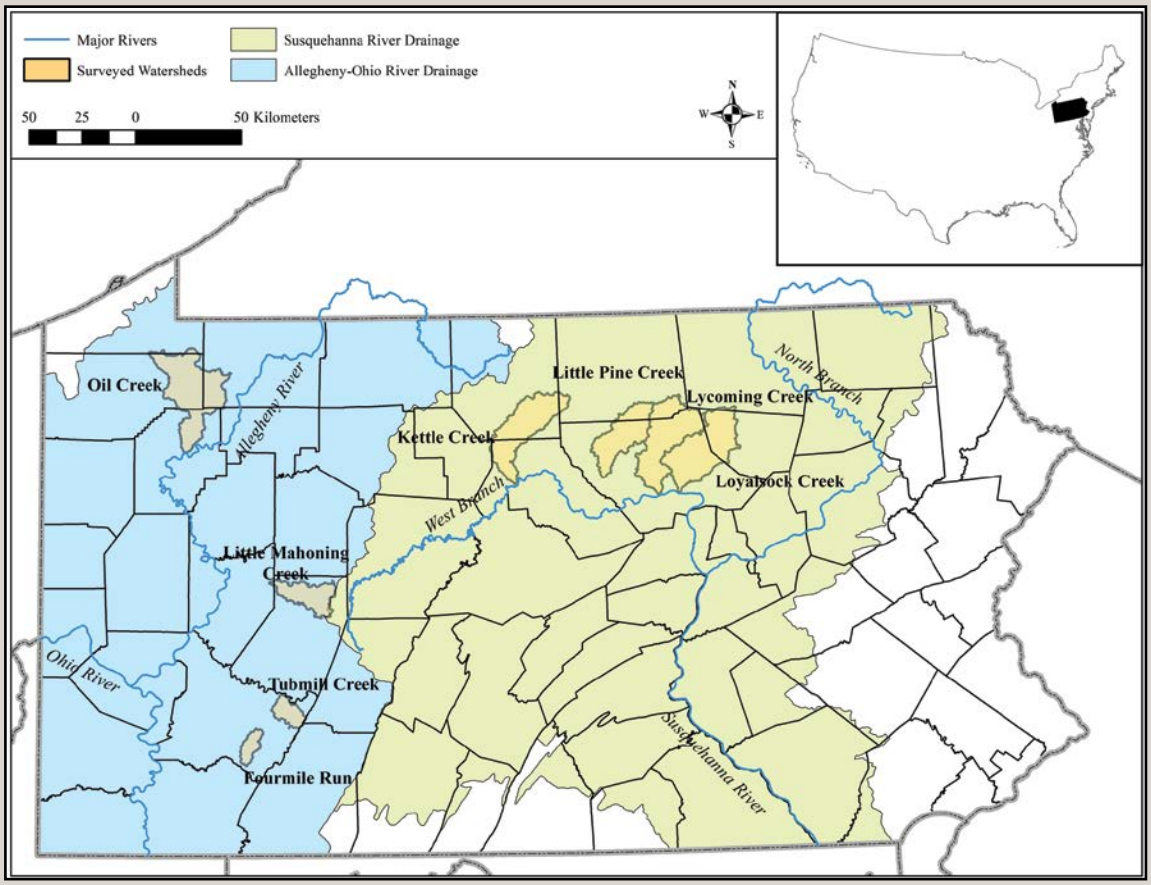

FIG. 1. Distribution of study sites associated with the Allegheny-Ohio River and Susquehanna River drainages, Pennsylvania, USA. Eastern Hellbenders (*Cryptobranchus alleganiensis alleganiensis*) were captured in four watersheds within the Appalachian Plateaus province and four watersheds within the north-central Ridge and Valleys province, and then tested for the fungal pathogen *Batrachochytrium dendrobatidis*. Exact sampling sites are not provided but general locations are indicated as surveyed watersheds.

Creek and Four Mile Run). In total, we assayed 12 pooled samples representing four populations associated with the Allegheny-Ohio River drainage and nine pooled samples representing four populations associated with the Susquehanna River drainage. Forty-three percent of pooled samples assayed provided positive test results for the presence of *Bd*, indicating the occurrence of *Bd*-infected hellbenders in four of the five counties that we examined (Table 1). We detected *Bd* among hellbender populations in two watersheds associated with the Allegheny-Ohio River drainage and two watersheds associated with the Susquehanna drainage. *Bd* was not detected on any swabs collected from hellbenders at Loyalsock Creek that were individually assayed. During the study period, we did not encounter any hellbenders with indications of morbidity or other obvious symptoms of poor health.

We found widespread occurrence of *Bd*, the amphibian chytrid pathogen, among *C. a. alleganiensis* in both major river drainages supporting breeding populations of hellbenders in Pennsylvania (Chapman, Petokas, and Regester, unpubl. data). These results represent the first systematic study of *Bd* occurrence on *C. a. alleganiensis* in Pennsylvania and the first documentation of *Bd* infection among stream-breeding salamanders in the state. Our findings, with those of Briggler et al. (2008) and Gonynor et al. (2011), confirm the occurrence of *Bd*-infected populations from widespread geographic regions within the hellbender's range and show that rates of *Bd* prevalence can be high (48%: Cooper Creek, Georgia) compared to other species of stream-breeding salamanders in the United States and Canada (0–22%: *Desmognathus* spp., *Dicamptodon aterrimus*, *Eurycea* spp., *Gyrinophilus porphyriticus*, *Pseudotriton ruber*: Byrne et al. 2008; Chatfield et al. 2009; Grant et al. 2008; Hossack et al. 2010; Ouellet et al. 2005; Rothermel et al. 2008; Timpe et al. 2008). Our results can be viewed as conservative with regard to the occurrence of *Bd* in Pennsylvania. The total number of hellbenders tested from four sites (Four Mile Run, Little Pine Creek, Loyalsock Creek, Oil Creek) was lower than the minimum sample size required to detect *Bd* in amphibian populations with relatively low rates of prevalence (Skerratt et al. 2008); hence, low sample size may have contributed to our lack of *Bd* detection in those watersheds.

Our study underscores the need for several areas of research. First, studies examining ecological predictors of *Bd* occurrence and testing for interactions between *Bd* prevalence and existing stressors are important for identifying high risk populations of hellbenders. In addition to the emerging pathogen *Bd*, hellbender populations in our region are subject to numerous threats to habitat quality (e.g., acid mine drainage, acid rain, increased sedimentation, and recent expansion of gas well drilling) that may potentially interact with *Bd* pathogenicity. In addition to continued long-term monitoring of hellbender population sizes, quantifying changes in *Bd* prevalence within and among populations and changes in *Bd*-status, condition, and survivorship among

TABLE 1. Distribution of the fungal pathogen *Batrachochytrium dendrobatidis* (*Bd*) among Eastern Hellbender (*Cryptobranchus a. alleganiensis*) populations by river drainage, county, and stream watershed in Pennsylvania, USA. Mean total length and mass (± 1SE, range) are provided for hellbenders tested for *Bd*. Swabs collected from salamanders in Loyalsock Creek were individually assayed.

River drainage	County	Stream watershed	Total length (cm)	Mass (g)	N	Pooled samples tested	Pooled samples *Bd*-positive

	Lycoming	Loyalsock Creek	39.3 ± 2.8 (25.5–52.3)	337.5 ± 57.7 (93.0–663.0)	8	0	0
	Lycoming	Lycoming Creek	41.5 ± 1.3 (29.4–51.5)	412.1 ± 33.6 (149.0–725.0)	31	5	2
Total					78	21	9

hellbender individuals and life stages, will provide insights into the disease ecology of this species and help prioritize conservation efforts. Finally, we identify a need for a coordinated, systematic approach to *Bd*-sampling in Pennsylvania, in collaboration with federal and state agencies, academic institutions, and nongovernmental organizations. Collaborative studies can efficiently increase our knowledge of chytridiomycosis in Pennsylvania by using standardized sampling regimes designed to encompass the taxonomic breadth of the state's amphibian fauna and promoting geographically widespread sampling efforts.

Acknowledgments.—This study was supported by an Undergraduate Research Grant (HS) and a Faculty Development Grant (KJR) from the Office of Research and Graduate Studies, Clarion University and by a Faculty Development Grant from the PA State System of Higher Education (KJR). Western Pennsylvania Conservancy efforts were supported by the Colcom Foundation and a private individual (EJC) and Lycoming College efforts were supported by the Degenstein Foundation (PJP). The study was conducted in accordance with permits issued by the Pennsylvania Fish and Boat Commission (KJR, EJC, and PJP) and by the DCNR Bureau of Parks (PJP). We complied with Guidelines for the Use of Live Amphibians and Reptiles in Field Research (ASIH, HR, and SSAR) and Institutional Care Guidelines. We are grateful to J. Bennet, L. Bobnar, J. Fiedor, G. Forestal, R. Hanlon, T. Hayes, K. Horrell, C. Itle-Sherry, S. Kerr, S. Kirn, L. Kirschman, E. Long, K. Maland, M. Mumford, N. Pinizzotto, B. Regester, P. Roberts, M. Schultze, T. Stark, A. Trexler, S. Unger, A. Viazanko, and B. Wright for assistance in the field.

First Record of *Batrachochytrium dendrobatidis* in Paraná, Brazil

Batrachochytrium dendrobatidis (*Bd*) has been reported in seven of twenty-seven federative states of Brazil, including Minas Gerais, Mato Grosso do Sul, Pernambuco, Rio de Janeiro, Rio Grande do Sul, Santa Catarina, and São Paulo (Toledo et al. 2006). Despite its apparent widespread occurrence in Brazil, there are many distributional gaps in our knowledge that are yet to be filled. Understanding the distribution of *Bd* is urgently needed for the development and implementation of amphibian conservation action plans (Verdade et al. 2012). Herein, we provide the first report *Bd* in the state of Paraná, Brazil.

Samples were collected on 26 March 2011 at the municipality of Morretes, within the Atlantic Forest (Fig. 1). Nine tadpoles of two species [*Hylodes cardosoi* (Hylodidae; N = 8) and *Hypsiboas faber* (Hylidae; N = 1)] were collected at the Estrada da Graciosa (PR-410, 25.351297°S, 48.882148°W, 470 m elev.) and examined in the laboratory for *Bd*. Two methods of chytrid diagnosis were applied: cytology (direct observation under the microscope without stains); and isolation of fungus strains in cultures (Longcore et al. 1999).

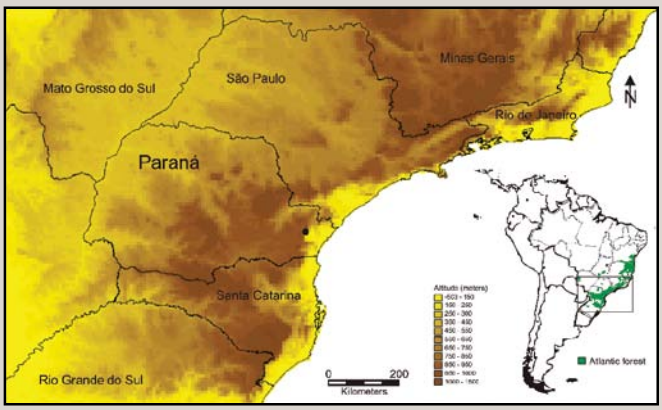

Fig. 1. Location of *Batrachochytrium dendrobatidis* sampling in the city of Morretes, state of Paraná, southern Brazil. SP = São Paulo, PR = Paraná, SC = Santa Catarina.

We detected *Bd* in 7 of 9 individuals we examined: 6 of 8 *Hylodes cardosoi* and 1 of 1 *Hypsiboas faber* were *Bd*-positive. Diagnosis was confirmed by the lack of keratin in mouthparts of the infected tadpoles, and the presence of *Bd* zoosporangia in the still keratinized regions of the mouth; some zoosporangia presented a medium septum (Berger et al. 2000) (Fig. 2). Following microscopic analysis, we isolated the *Bd* fungus (strain CLFT 024) in solid growth medium cultures of 1% tryptone agar (Fig. 2).

Our detection of *Bd* from Morretes fills a 200 km knowledge gap in the distribution of *Bd* in Brazil. The site is approximately 100 km north of São Bento do Sul, Santa Catarina, and 100 km

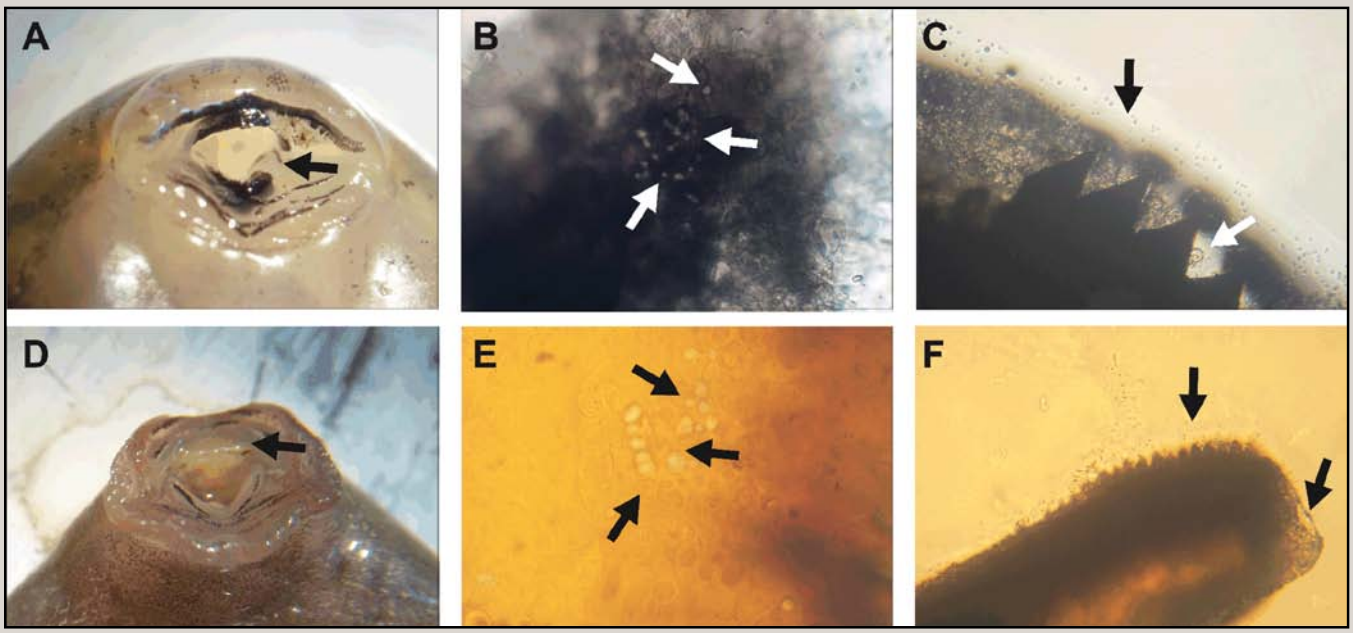

FIG. 2. *Batrachochytrium dendrobatidis* diagnosis by visual examination (A and D: lack of keratin in the tadpole mouthparts indicated by an arrow); cytology (B and E: optical microscope at 400× amplification, arrows indicating zoosporangia), and isolation (C and F: mTGh culture medium, with the arrows indicating zoospores and zoosporangia) methods. Top row of images A–C were taken from *Hylodes cardosoi*; bottom row images D–F were taken from *Hypsiboas faber*, as labeled.

south of Apiaí, São Paulo, which were the nearest sites last reported (Carnaval et al. 2006; Toledo et al. 2006). Also, this site is the type and only known locality of *Cycloramphus rhyakonastes* (Cycloramphidae; Heyer 1983), which is listed as endangered for the state (Mikich and Bérnils 2004). As the tadpoles of both species (*H. cardosoi* and *H. faber*) may live for one year or more in the water bodies, they may be serving as reservoirs of the fungus and infecting other species in the area. Hence, further *Bd* monitoring at this site is warranted to assess the potential threat of chytridiomycosis to these populations.

Other *Bd* distributional gaps exist in Brazil. For example, the occurrence of the fungus has not been studied between the states of Rio de Janeiro and Pernambuco, indicating a lack of sampling across the Atlantic Forest.

Three *Bd* strains have been previously isolated from Brazil; two (CLFT 001/10 and CLFT 021/01) from Serra do Japi, Jundiaí and Cabreúva, São Paulo, and one (CLFT 023/01) in Monte Verde, Camanducaia, Minas Gerais (unpublished data). We report the isolation of a fourth strain (CLFT 024) from the Brazilian Atlantic Forest. The isolation of strains is important because it provides the basis for studies of fungal molecular biology, virology, biogeography, physiology, morphology, and amphibian conservation. In particular, amphibian host-specific virulence patterns of different *Bd* strains are not well known, which could have direct relevance to amphibian conservation efforts.

Acknowledgments.—We thank Diogo Henrique Moraes for help with laboratory work and Mirtis M. G. Ferraz for support and enthusiasm in microbiology. FAPESP (Fundação de Amparo à Pesquisa do Estado de São Paulo) provided a grant (08/50325-5) and scholarships (08/52847-9 and 2010/15259-1).

Resumo.—Reportamos aqui pela primeira vez a ocorrência do fungo quitrídio (*Batrachochytrium dendrobatidis*) no estado brasileiro do Paraná. A descoberta é preocupante, pois espécies endêmicas e ameaçadas de extinção vivem nos mesmos corpos d'água onde foi encontrado o fungo, organismo que pode ser letal para anfíbios.

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of a species' range, and thereby permit a more significant interpretation of its biology.

These geographic distribution records will be accepted in a **standard format** only, and all authors *must* adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (for the United States and Canada as it appears in Crother [ed.] 2008. *Scientific and Standard English Names of Amphibians and Reptiles of North America North of Mexico*. SSAR Herpetol. Circ. 37:1–84, gratis PDF available (http://www.ssarherps.org/pages/HerpCommNames.php); for Mexico as it appears in Liner and Casas-Andreu 2008, *Standard Spanish, English and Scientific Names of the Amphibians and Reptiles of Mexico*. Herpetol. Circ. 38:1–162), LOCALITY (use metric for distances and give precise locality data, including lat/long coordinates in **decimal degrees** and cite the map datum used), DATE (day-month-year), COLLECTOR, VERIFIED BY (*cannot* be verified by an author; curator at an institutional collection is preferred), PLACE OF DEPOSITION (where applicable, use standardized collection designations as they appear in Leviton et al. 1985, *Standard Symbolic Codes for Institutional Resource Collections in Herpetology and Ichthyology*, Copeia 1985[3]:802–832) and CATALOG NUMBER (required), COMMENTS (brief), CITATIONS (brief and must adhere to format used in this section; these should provide a geographic context for the new record), SUBMITTED BY (give name and address in full—spell out state or province names—no abbreviations). Please include distance from nearest previously known record (provide a citation or refer to existing vouchered material to substantiate your report). If publishing specific locality information for a rare or endangered species has the potential to jeopardize that population, please consult with the Section Editor at time of record submission. If field work and/or specimen collection occurred where permits were required, please include permit number(s) and authorizing agency in the text of the note.

Some further comments. The role of the "Standard Names" lists (noted above) is to standardize English names and comment on the current scientific names. Scientific names are hypotheses (or at least represent them) and as such their usage should not be dictated by a list, society, or journal.

If the locality reported is clearly outside of the natural range of the species, a statement to that effect should be included in the note, along with relevant citation(s). Additionally, if an "introduced" species has become established at the new locality, please include supporting observations, as well as information concerning means of introduction and source population, if known.

Additionally, this geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens that have been placed in a university or museum collection (private collection depository records are discouraged; institutional collection records will receive precedence in case of conflict). A good quality photograph (print, slide, or digital file) may substitute for a preserved specimen *only* when the live specimen could not be collected for the following reasons: it was a protected species, it was found in a protected area, or the logistics of preservation were prohibitive (such as large turtles or crocodilians). Photographic vouchers *must* be deposited in a university or museum collection along with complete locality data, and the photographic catalog number(s) must be included in the same manner as a preserved record. Before you submit a manuscript to us, check Censky (1988, *Index to Geographic Distribution Records in Herpetological Review: 1967–1986*; available from the SSAR Publications Secretary), subsequent issues of *Herpetological Review*, and other sources to make sure you are not duplicating a previously published record. The responsibility for checking literature for previously documented range extensions lies with authors. **Do not submit range extensions unless a thorough literature review has been completed.**

Please submit any geographic distribution records in the **standard format only** to one of the Section Co-editors: **Alan M. Richmond** (USA & Canada records only); **Jerry D. Johnson** (Mexico and Central America, including the Caribbean Basin); **Indraneil Das** (all Old World records); or **Gustavo J. Scrocchi** (South American records). Short manuscripts are discouraged, and are only acceptable when data cannot be presented adequately in the standard format. **Electronic submission of manuscripts is required** (as Microsoft Word or Rich Text format [rtf] files, as e-mail attachments)**.** Refer to inside front cover for e-mail addresses of section editors.

Recommended citation for new distribution records appearing in this section is: Schmitz, A., and T. Ziegler. 2003. Geographic distribution: *Sphenomorphus rufocaudatus*. Herpetol. Rev. 34:385.

CAUDATA — SALAMANDERS

***AMBYSTOMA MACULATUM* (Spotted Salamander).** USA: GEORGIA: Gwinnett Co.: Mill Creek Nature Center (34.06076°N, 83.98080°W, WGS 84; elev. ~312 m). 7 October 2011. Cyndi Moore and Robert L. Hill. Verified by John Jensen. UTADC 6979. New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. Univ. of Georgia Press, Athens. 575 pp.); has been previously observed in Gwinnett Co. though this report represents the first vouchered specimen. This species has also been documented in neighboring Fulton, Dekalb, Rockdale, and Walton counties. An adult specimen (~100 mm SVL) was discovered under a log ~3 m S of the hiking path and ~0.25 km from preserve entrance at Mall of Georgia Boulevard. It was photographed and returned.

ROBERT L. HILL, Department of Herpetology, Zoo Atlanta, Atlanta, Georgia 30315, USA; e-mail: rhill@zooatlanta.org.

***DESMOGNATHUS FUSCUS* (Northern Dusky Salamander).** CANADA: NEW BRUNSWICK: Victoria Co.: Unnamed stream in Hillandover (46.71965°N, 67.7371°W; WGS 84). 20 July 2011. Gregor F. M. Jongsma, Wendy Wolman, Luke DeCicco, and Andi Emrich. New Brunswick Museum (NBM 009237–009238). New county record. Gorham (1970. The Amphibians and Reptiles of New Brunswick. New Brunswick Museum, Saint John) notes that along the New Brunswick-Maine border region *D. fuscus* occurs only as far north as southern Carleton Co. (south of Victoria Co.) and more recently, McAlpine (2010. *In* D. F. McAlpine and I. M. Smith [eds.], Assessment of Species Diversity in

Atlantic Maritime Ecozone, pp. 613–631. NRC Research Press, Ottawa) listed the species as hypothetical for the ecoregion that includes Victoria Co. Extends the known range of this species 60 km N from the nearest documented locality, near Woodstock (46.15814°N, 67.63716°W, WGS 84; NBM 009096). York Co.: Unnamed stream 4.6 ESE of Stanley (46.2695°N, 66.67605°W, WGS 84). 18 August 2010. Gregor F. M. Jongsma. NBM 009077. The individual, collected near Stanley, extends the range of *D. fuscus* 29 km N from the nearest documented locality, Killarney Park, Fredericton, York Co. (46.01793°N, 66.62197°W WGS 84; NBM 009075). All specimens were verified by Donald F. McAlpine.

GREGOR F. M. JONGSMA, 366 George Street, Apt. 1B, Fredericton, New Brunswick, Canada; e-mail: Gregor.Jongsma@gmail.com.

***EURYCEA CIRRIGERA* (Southern Two-lined Salamander).** USA: TENNESSEE: Weakley Co.: Beech Ridge Unit of the Obion Wildlife Management Area (36.228594°N, 88.942949°W; WGS 84). 12 November 2011. Tom Blanchard. Verified by A. Floyd Scott. Austin Peay State University (APSU 19185). New county record (Redmond and Scott 1996. [updated 29 November 2011] Atlas of Amphibians in Tennessee. Misc. Publ. No. 12. Center for Field Biology, Austin Peay State University. Clarksville, Tennessee. 94 pp. Internet version available at http://www.apsu.edu/amatlas; updated 29 Nov 2011, accessed 15 Nov 2011). Adult male found under log in dry bed of periodically flooded, forested wetland.

TOM BLANCHARD, Department of Biological Sciences, University of Tennessee at Martin, Martin Tennessee 38238, USA; e-mail: tblanch@utm.edu.

***EURYCEA QUADRIDIGITATA* (Dwarf Salamander).** USA: ARKANSAS: Jefferson Co.: 6.6 km NW of White Hall (34.329828°N, 92.124281°W; WGS 84). 20 April 2001. H. W. Robison. Verified by S. E. Trauth. Arkansas State University Museum of Zoology Herpetological Collection (ASUMZ 31901). New county record; partially fills a hiatus among Cleveland (Trauth et al. 2004. Amphibians and Reptiles of Arkansas. Univ. Arkansas Press, Fayetteville. 421 pp.) and Grant (McAllister and Robison 2012. Herpetol. Rev. 43[*in press*]) counties. This records helps extend the range of *E. quadridigitata* further to the northeast in the state.

CHRIS T. McALLISTER, Science and Mathematics Division, Eastern Oklahoma State College, 2805 NE Lincoln Road, Idabel, Oklahoma 74745, USA (e-mail: cmcallister@se.edu); **HENRY W. ROBISON**, Department of Biology, Southern Arkansas University, Magnolia, Arkansas 71754, USA (e-mail: hwrobison@yahoo.com).

***EURYCEA QUADRIDIGITATA* (Dwarf Salamander).** USA: LOUISIANA: Acadia Parish: Bayou Plaquemine Brule area (30.1990°N, 92.5337°W; WGS 84). 28 October 2005. Glen Maglalang. Verified by Jeff Boundy. Louisiana State University Eunice Vertebrate Collection (LSUE 2262). New parish record (Dundee and Rossman 1989. The Amphibians and Reptiles of Louisiana. Louisiana St. Univ. Press, Baton Rouge. 300 pp.). This record fills the gap between Jefferson Davis and Lafayette parishes.

AVERY A. WILLIAMS, Division of Sciences and Mathematics, Louisiana State University Eunice, Eunice, Louisiana 70535, USA; e-mail: aaavery@aol.com.

***NECTURUS MACULOSUS* (Mudpuppy).** USA: TENNESSEE: Cannon Co.: Brawleys Fork of East Fork Stones River, tributary to Stones River. Accessed from the junction of Tennessee Hwy 64 (Bradyville Road) and Barker Road (35.801944°N, 86.150833°W; NAD 27). 18 March 2011. Matthew D. Wagner and Shawn P. Settle. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 19118 color photo). New county record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12, The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp. [Hard copy and Internet versions, the latter of which includes links to information on Tennessee amphibians having appeared since 1996, http://www.apsu.edu/amatlas/, accessed 3 August 2011]). One adult caught via electrofishing on the downstream side of a bridge pylon.

MATTHEW D. WAGNER, Department of Biology, Austin Peay State University, Clarksville, Tennessee 37040, USA; e-mail: mwagner5@my.apsu.edu.

***NOTOPHTHALMUS VIRIDESCENS LOUISIANENSIS* (Central Newt).** USA: ARKANSAS: Jefferson Co.: Tar Camp Creek at US 65/I-530 (34.431264°N, 92.193714°W; WGS 84). 12 May 2003. B. Deeds. Verified by S. E. Trauth. Arkansas State University Museum of Zoology Herpetological Collection (ASUMZ 31902). New county record filling a distributional gap among Arkansas (McAllister and Robison 2009. Herpetol. Rev. 40:245), Lincoln (Robison and McAllister 2008. Herpetol. Rev. 39:104) and Lonoke (Plummer and McKenzie 2008. Herpetol. Rev. 39:104) counties.

CHRIS T. McALLISTER, Science and Mathematics Division, Eastern Oklahoma State College, 2805 NE Lincoln Road, Idabel, Oklahoma 74745, USA (e-mail: cmcallister@se.edu)**; HENRY W. ROBISON**, Department of Biology, Southern Arkansas University, Magnolia, Arkansas 71754, USA (e-mail: hwrobison@yahoo.com).

***PSEUDOTRITON RUBER RUBER* (Northern Red Salamander).** USA: SOUTH CAROLINA: Darlington Co.: Lauther's Lake, about 0.5 km N boat ramp, 13.3 km ENE of Darlington (34.32899°N, 79.72456°W; WGS 84). 29 March 2006. Jeffrey D. Camper. Verified by D. A. Beamer. Photographic voucher deposited in the Clemson University Vertebrate Collections (CUSC 1152). New county record. Extends the range of the species from the fall line sand hills southeast to the upper coastal plain. First record on the coastal plain in northern South Carolina (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington, D.C. xvi + 587 pp.). Two specimens collected under logs in a seep during early afternoon.

JEFFREY D. CAMPER, Department of Biology, Francis Marion University, Florence, South Carolina 29506, USA (e-mail: jcamper@fmarion.edu); **STEPHEN H. BENNETT**, South Carolina Department of Natural Resources, Columbia, South Carolina 29202, USA (e-mail: BennettS@dnr.sc.gov).

***STEREOCHILUS MARGINATUS* (Many-lined Salamander).** USA: GEORGIA: Telfair Co.: 3.3 km ENE Jacksonville, State Hwy 117 at Lampkin Branch (31.816883°N, 82.944207°W; NAD 83). 22 July 2010. K. Stohlgren and D. Stevenson. Verified by Lance D. McBrayer. GSU 11917. First record for county (Jensen et al. [eds.] 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.) Extends the species range ca. 62 km N of the nearest record (Satilla River drainage, Atkinson Co., Georgia). Additionally, this record extends the known range in the Altamaha River drainage ca. 83 km to the west of the nearest record (Tattnall Co., Georgia; Williamson and Moulis 1994. Distribution of Amphibians and Reptiles in Georgia. Savannah Sci. Mus. Spec. Publ. No. 3, Savannah, Georgia). Adult found in mucky seepage area within blackwater creek swamp.

KEVIN M. STOHLGREN and **DIRK J. STEVENSON,** The Orianne Society, Indigo Snake Initiative, 579 Hwy 441 South, Clayton, Georgia 30525, USA.

ANURA — FROGS

***DENDROPSOPHUS SANBORNI* (Sanborn's Treefrog)**. BRAZIL: MATO GROSSO DO SUL: Municipality of Três Lagoas: Fazenda Santa Marina (20.3636°S, 52.5815°W; SAD 69). 10 October 2010. F. L. Souza, P. Landgref-Filho, and M. N. Godoi. Coleção Zoológica de Referência da Universidade Federal de Mato Grosso do Sul, Campo Grande, MS, Brazil (ZUFMS-AMP 2156–2158), Museu Nacional, Rio de Janeiro, RJ, Brazil (MNRJ 73486–73488). Verified by U. Caramaschi. This species was previously known in western Rio Grande de Sul, Santa Catarina, Paraná, São Paulo, and Mato Grosso (Brazil), northern Argentina, Uruguay, and Oriental region of Paraguay (Ribeiro et al. 2005. Biota Neotrop. 5[2]:1–15). We present the first record of this species from Mato Grosso do Sul State, filling a distributional gap of 915 km across central Brazil, between the closest published localities, 330 km W from records in São Paulo (Vasconcelos and Rossa-Ferres 2008. Phyllomedusa 7[2]:127–142) and 624 km NW from records in Mato Grosso (Ribeiro et al., *op. cit.*). Individuals were associated with veredas (palm swamp) in a typical Cerrado vegetation.

PAULO LANDGREF FILHO (e-mail: paulograf@yahoo.com.br); **MAURICIO NEVES GODOI**, Programa de Pós-Graduação em Ecologia e Conservação, Universidade Federal do Mato Grosso do Sul, Campo Grande, MS, Brazil (e-mail: mauricioecologia@hotmail.com); **FRANCO LEANDRO SOUZA**, Centro de Ciências Biológicas e da Saúde, Universidade Federal de Mato Grosso do Sul, CEP 79070-900 Campo Grande, MS, Brazil (e-mail: franco.souza@ufms.br).

***HYLA CINEREA* (Green Treefrog)**. USA: MISSOURI: Jasper Co.: Oronogo, ca.14 air km NNE of Joplin (37.201074°N, 94.463260°W, WGS84; elev. 283 m). 04 September 2010. Nathan A. Mitchell. Verified by Richard Daniel. University of Missouri Columbia (UMC 1841P; digital image). New county record (Daniel and Edmond 2010. Atlas of Missouri Amphibians and Reptiles for 2009. <http://atlas.moherp.org/pubs/atlas09.pdf>). Abundant male calls recorded at wetland ca. 0.70 air km SSW of specimen collection point on 12 June 2011.

NATHAN A. MITCHELL, 609 Sarah Ct., Oronogo, Missouri 64855, USA; e-mail: nmitchell46@gmail.com.

***HYLA CINEREA* (Green Treefrog)**. USA: NEW JERSEY: Salem Co.: 75.542538°N, 39.617964°W (WGS 1984). 02 June 2011. Karena DiLeo. Verified by David Golden. ANSP 36840. New state record. (Aresco 1996. Am. Midl. Nat. 135[2]:293–298). Nearest previously known record in Delaware (Hammerson and Hedges 2004. *In* IUCN 2011. IUCN Red List of Threatened Species. version 2011.2; <www.iucnredlist.org>. Downloaded 07 November 2011).

KARENA DILEO, Endangered and Nongame Species Program, New Jersey Division of Fish and Wildlife, 501 East State Street, Trenton, New Jersey 08625, USA; e-mail: karena.dileo@dep.state.nj.us.

***HYLA SQUIRELLA* (Squirrel Treefrog)**. USA: GEORGIA: Baldwin Co.: City of Milledgeville (33.094111°N, 83.247077°W; WGS84). 27 September 2010. Sergio Patitucci Saieh and Dennis Parmley. Verified by John Jensen. GCH 5240. First county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.). Single adult collected at apartment complex during heavy rain.

SERGIO PATITUCCI SAIEH and **DENNIS PARMLEY**, Department of Biological and Environmental Sciences, Georgia College & State University, Milledgeville, Georgia 31061, USA (e-mail: dennis.parmley@gcsu.edu).

***KALOULA TAPROBANICA* (Sri Lankan Bull Frog)**. BANGLADESH: DHAKA DIVISION: Bangladesh Agricultural University Campus (24.7196°N, 90.4267°E, > 18 m elev.). 11 June 2008. Mahmudul Hasan. Department of Fisheries Biology and Genetics, Bangladesh Agricultural University, Mymensingh, Bangladesh. Specimen deposited at Institute for Amphibian Biology, Hiroshima University, Japan (IABHU F5013). Verified by Mitsuru Kuramoto. First locality record for Mymensingh District, Bangladesh. Nearest population reported from Madhupur National Park, Tangail District (ca. 38 km to W; Reza and Mahony 2007. Herptol. Rev. 38:348). Other records from Assam, India, > 200 km to NE and Kolkata, West Bengal, India > 300 km to SW of this locality (Dutta 1997. Amphibians of India and Sri Lanka [Checklist and Bibliography]. Odyssey Publishing House, Bhubaneswar. xiii + 343 + xxii pp.). Supported by Grant-in-Aids for Scientific Research (C) (Nos. 17570082 and 20510216) to M. Sumida from Ministry of Education, Culture, Sports, Science and Technology, Japan.

M. HASAN, Institute for Amphibian Biology, Hiroshima University, Hiroshima 739-8526, Japan. (e-mail: mhasan_fish@yahoo.com); and **M. SUMIDA**, Institute for Amphibian Biology, Hiroshima University, Hiroshima 739-8526, Japan. (e-mail: msumida@hiroshima-u.ac.jp).

***LEPTODACTYLUS POECILOCHILUS* (Turbo White-lipped Frog)**. COSTA RICA: HEREDIA: San Ramón de Sarapiquí: Braulio Carrillo National Park, Estación El Ceibo (ca. 10.327363°N, 84.078677°W; WGS 84), 525 m elev. 10 January 2005. S. Mohammadi and J. W. Streicher. Verified by W. Ronald Heyer. USNM 561433; UTADC 526. First record for Heredia and one of only a few records from the Atlantic versant of Costa Rica (Savage 2002. Amphibians and Reptiles of Costa Rica: A Herpetofauna Between Two Continents, Between Two Seas. University of Chicago Press. xx + 934 pp.). The frog was caught at 2005 h during a light rain in a pasture bordering a forested portion of Braulia Carrillo National Park. It was secured under MINAE permit #0098520004 (License #38312) issued to both of us.

JEFFREY W. STREICHER, Amphibian and Reptile Diversity Research Center, Department of Biology, University of Texas at Arlington, Arlington, Texas 76019, USA (e-mail: streicher@uta.edu); **SHABNAM MOHAMMADI,** Department of Biology, Utah State University, Logan, Utah 84322, USA (e-mail: shab.mohammadi@gmail.com).

***LITHOBATES CATESBEIANUS* (American Bullfrog)**. USA: KANSAS: Kiowa Co.: Greensburg (37.613774°N, 99.300071°W; elev. 679 m). 7 May 2011. Brian Hubbs. Verified by Neftali Camacho. Natural History Museum of Los Angeles County photo voucher LACM PC 1556. New county record (Collins 2010. Amphibians, Reptiles, and Turtles in Kansas. Sternberg Museum of Natural History, Fort Hays State University, Hays, Kansas. 312 pp.).

BRIAN HUBBS, PO Box 26407, Tempe, Arizona 85285, USA; e-mail: tricolorbrian@hotmail.com.

***LITHOBATES* [= *RANA*] *CATESBEIANUS* (American Bullfrog)**. USA: NEW MEXICO: Taos Co.: Rio Grande, ca. 3.2 km N (upriver) of Pilar (36.29367°N, 105.77918°W, WGS 84; elev. 1830 m). 26 September 2009. J. N. Stuart. One juvenile photographed; many present. Digital Archives, Division of Herpetology, Biodiversity Institute, University of Kansas (KUDA 012246).

Los Alamos Co.: Pajarito Spring, on W side of White Rock Canyon above the Rio Grande (35.80396°N, 106.19689°W, WGS84; elev. 1707 m). 4 April 2010. M. Bjorklund. Adult male (KUDA 012251). Tadpoles were also found at Pajarito Spring, 16 April

2010 (KUDA 012252). All verified by Charles W. Painter from photographs. New county records (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xix + 431 pp.).

JAMES N. STUART, New Mexico Department of Game and Fish, Conservation Services Division, Santa Fe, New Mexico 87504-5112, USA (e-mail: james.stuart@state.nm.us); **MARK BJORKLUND**, 292 Aragon Avenue, Los Alamos, New Mexico 87544, USA (e-mail: mdbhhb@q.com).

***LITHOBATES HECKSCHERI* (River Frog)**. USA: ALABAMA: Bullock Co.: The Wehle Tract (32.03151°N, 85.47390°W; WGS 84). 19 September 2011. Brian Folt. Verified by Craig Guyer. Auburn University Herpetological collection (photo voucher AHAP-D 326a,b). First county record and the first voucher for this species in Alabama since 1975 (Mount 1975. The Reptiles and Amphibians of Alabama. Auburn University Agricultural Experiment Station, Auburn, Alabama. vii +347 pp.).

Found under log along shoreline of impoundment pond; captured by hand. Previously, *L. heckscheri* had been verified in only three localities in Alabama: one each in Mobile, Baldwin, and Escambia counties (Mount 1975, *op. cit.)*. Whereas the historic Alabama localities are exclusively within the Lower Coastal Plains, this new record is farther north (171 km ENE from the nearest known location in Alabama), situated within the transitional zone between the Red Hills and Black Belt regions. Because this species is thought to be restricted to the Coastal Plains (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.), this record is novel and suggests that other habitats might be suitable.

BRIAN P. FOLT, Auburn University, Department of Biological Sciences, 330 Funchess Hall, Auburn, Alabama 36849, USA; e-mail: brian.folt@gmail.com.

***MELANOPHRYNISCUS KLAPPENBACHI* (Klappenbach's Red-bellied Toad)**. BRAZIL, MATO GROSSO DO SUL, Municipality of Porto Murtinho, Fazenda Santo Antônio (21.527163°S, 57.832186°W, SAD 69); Fazenda Carandá (21.554553°S, 57.781036°W, SAD 69). 30 May 2011. I. B. Amaral, P. Landgref-Filho, and D. I. Ferreira. Coleção Herpetológica do Museu de Ciências e Tecnologia PUCRS, Porto alegre, RS, Brazil (MCP/PUC/RS 11944-11946, 11949-11969). Fazenda Patolá (21.686749°S, 57.719681°W, WGS 1984). 27 October 2008. F. L. Souza, M. Uetanabaro, and P. Landgref-Filho. Coleção Zoológica de Referência da Universidade Federal de Mato Grosso do Sul, Campo Grande, MS, Brazil (ZUFMS AMP 1046). Verified by T. Grant. This species was previously known for Paraguay (southern Alto Paraguay, Presidente Hayes, and Ñeembucú Department: Brusquetti and Lavilla 2006. Cuad. Herpetol. 20[2]:1–79) and Argentina (Chaco, Formosa, and Northern Santa Fe and Santiago del Estero provinces: Baldo 2001. Cuad. Herpetol. 15[2]:141–142). First country record. The study site is located in the southern Pantanal, at the left bank of Paraguay River, the only Brazilian region encompassed by the Chaco biome. New localities extends know distribution 90 km N of Alto Paraguay, Paraguay, in Municipality of Porto Murtinho, Brazil.

IVAN BOREL AMARAL, Centro Nacional de Pesquisa e Conservação de Répteis e Anfíbios – RAN/ Instituto Chico Mendes de Conservação da Biodiversidade - ICMBio (e-mail: ivan.amaral@icmbio.gov.br); **PAULO LANDGREF FILHO** (e-mail: paulograf@yahoo.com.br); **FRANCO LEANDRO SOUZA,** Centro de Ciências Biológicas e da Saúde, Universidade Federal de Mato Grosso do Sul, CEP 79070-900 Campo Grande, MS, Brazil (e-mail: franco.souza@ufms.br) and **MASAO UETANABARO** (e-mail: masao.uetanabaro@gmail.com).

***PHLYCTIMANTIS LEONARDI* (Olive Striped Frog)**. CAMEROON: EAST PROVINCE: Ngoum-Bandi (aka PK27), S border of Lobéké National Park (02.13881°N, 15.65567°E; WGS 84; 620 m elev.). 28 May 2010. Václav Gvodík and Oldich Kopecký. National Museum, Prague, Czech Republic. NMP6V 74437/1–5. Verified by Jean-Louis Amiet and Mark-Oliver Rödel. Previously recorded in Gabon, Equatorial Guinea (mainland), Republic of Congo, and western Democratic Republic of Congo (Schiøtz et al. 2004. *In* IUCN 2011. IUCN Red List of Threatened Species, ver. 2011.1. <www.iucnredlist.org>). Four adult males (SVL 47.9–51.0 mm) and one adult female (SVL 54.8 mm) collected from small shallow pond at edge of primary forest. Males calling from grassy inundated banks and low bushes from dusk until ca. 2400 h. Pairs in amplexus and numerous tadpoles also observed. New record extends known range by ca. 50 km N from nearest localities in Republic of Congo. First species record for Cameroon and first record of genus from Cameroonian Congo Basin (cf. Amiet 2007. Rev. Suisse Zool. 114:87–126).

VÁCLAV GVOŽDÍK, Institute of Animal Physiology and Genetics, Academy of Sciences of the Czech Republic, Rumburska 89, CZ 277 21 Libechov & National Museum, Department of Zoology, Cirkusova 1740, CZ 193 00 Prague, Czech Republic (e-mail: vgvozdik@email.cz); **OLDŘICH KOPECKÝ,** Department of Zoology and Fisheries, Faculty of Agrobiology, Food and Natural Resources, Czech University of Life Sciences Prague, Kamycka 957, CZ 165 21 Prague, Czech Republic (e-mail: kopeckyo@af.czu.cz).

***PSEUDACRIS CLARKII* (Spotted Chorus Frog)**. USA: NEW MEXICO: Quay Co.: Playa lake located on the south side of NM Hwy 231, 2.0 km W of intersection of NM Hwy 469 and NM Hwy 23; ca. 2.7 air km SW of Wheatland (34.89232°N, 103.37679°W, NAD1983; elev. 1440 m). 05 August 2011. Jessica A. Kissner. Verified by Toby Hibbitts. University of Kansas (KUDA digital images 012215–012218, and 012219 audio). First state record (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. University of New Mexico Press, Albuquerque, New Mexico). Nearest previous record was at Muleshoe National Wildlife Refuge in Muleshoe, Texas, ca. 117 km airline SE from the new locality. At 2144 h, two adult males were heard and seen calling from the base of emergent vegetation after a 0.5 mm rainfall. Air temperature was 20.9°C and humidity was 83%, with cloudy skies and an average wind speed of 5.6 mph.

Field work was conducted under permit number 3318 issued by New Mexico Department of Game and Fish.

JESSICA A. KISSNER (e-mail: jessica.kissner@ttu.edu) and **KERRY L. GRIFFIS-KYLE,** Texas Tech University, Department of Natural Resources Management, Lubbock, Texas 79409, USA (e-mail: kerry.griffis-kyle@ttu.edu).

***PSEUDACRIS MACULATA* (Boreal Chorus Frog)**. USA: NEBRASKA: Harlan Co.: Republican City (40.089455°N, 99.213149°W; elev. 612 m). 22 May 2011. Brian Hubbs. Verified by Dan Fogell. Natural History Museum of Los Angeles County photo voucher LACM PC 1563. New county record (Ballinger et al. 2010. Amphibians and Reptiles of Nebraska. Rusty Lizard Press, Oro Valley, Arizona. 400 pp.; Fogell 2010. The Amphibians and Reptiles of Nebraska. University of Nebraska Press, Lincoln, Nebraska. 158 pp.). Frog found in flooded roadside ditch.

XENOPUS LAEVIS **(African Clawed Frog)**. MÉXICO: BAJA CALIFORNIA: Municipality of Rosarito: Bocana Cantamar (32.22969°N, 116.92132°W, WGS 84), 2 m elev. 27 March 2011. G. Ruiz-Campos and A. Andreu-Soler. Verified by Clark R. Mahrdt. UABC 2029. First vouchered record for México and Baja California, and a 40 km WSW range extension from an undocumented observational record from Río las Palmas, Cañon el Alamo, NE El Testerazo (Mahrdt et al. 2003. Herpetol. Rev. 34:256–257). Even though *X. laevis* has also been reported by others to occur in México, most likely in northern Baja California (e.g., Álvarez-Romero et al. 2008. Animales Exóticos en México: Una Amenaza para la Biodiversidad. CONABIO, Instituto de Ecología, UNAM, SEMARNAT, México, D.F. 518 pp.; Liner 2007. Occas. Pap. Mus. Nat. Sci., Louisiana State Univ. 80:1–59; Tinsley and McCoid 1996. *In* R. C. Tinsley [ed.], The Biology of *Xenopus*. Symposia of the Zoological Society of London, No. 68, pp. 81–94. Clarendon Press, Oxford, England), no vouchered specimens are available. The adult frog was captured by a minnow trap in a stream lined primarily by California Tule (*Scirpus californicus*).

GORGONIO RUIZ-CAMPOS, Laboratorio de Vertebrados, Facultad de Ciencias, Universidad Autonoma de Baja California, km 103 carret. Tijuana-Ensenada, Ensenada, Baja California, México (e-mail: gruiz@uabc.edu.mx); **JORGE H. VALDEZ-VILLAVICENCIO**, Centro de Investigaciones Biológicas del Noroeste (CIBNOR), Mar Bermejo #195 Colonia Playa Palo de Santa Rita, La Paz, Baja California Sur, 23090, México (e-mail: jhvaldez@cibnor.mx).

XENOPUS PYGMAEUS **(Bouchia Clawed Frog)**. GABON: HAUT OGOOÉ PROVINCE: Batéké Plateau National Park, Camp Ntsa (1.9816°S, 14.0011°E). 30 May 2011. B. M. Zimkus and J. G. Larson. Museum of Comparative Zoology (MCZ A-147875). Verified by José Rosado. Verification supported by mitochondrial data from 16S ribosomal DNA (Genbank Accession JQ302191). Species ranges from Bagandou, Etoi and Bouchia in southern Central African Republic, east to northeastern Democratic Republic Congo and Semliki in western Uganda. First confirmed country record in Gabon, extending range > 750 km SW from type locality in Bouchia, Central African Republic. Presence in Batéké Plateau National Park, southwestern Gabon suggests a distribution across border in Republic of Congo, for which there are currently no records.

BREDA M. ZIMKUS and **JOANNA G. LARSON**, Department of Organismic and Evolutionary Biology, Harvard University, 26 Oxford Street, Museum of Comparative Zoology, Cambridge, Massachusetts 02138, USA (e-mail: bzimkus@oeb.harvard.edu).

***TRACHEMYS SCRIPTA ELEGANS* (Red-eared Slider)**. USA: Texas: Goliad Co.: Naval Auxiliary Landing Field Goliad near a shallow pond (28.6112°N, 97.6124°W; WGS 84). Carapace collected on 19 October 2011. F. Weaver, C. Giggleman, and N. Mitton. Verified by Travis J. Laduc. Texas Natural History Collections (TNHC 85064). New county record (Dixon 2000. Amphibians and Reptiles of Texas, 2nd ed. Texas A&M Univ. Press. College Station. 421 pp.). One juvenile specimen was seined at ca. 1 m depth at the same location, 19 April 2011 by C. Giggleman, A. Miller, P. Clements, and N. Mitton .

FRANKLIN J. WEAVER (e-mail: frank_weaver@fws.gov) and **CRAIG GIGGLEMAN**, U.S. Fish and Wildlife Service, Corpus Christi Ecological Services Field Office, 6300 Ocean Drive, Classroom West, Corpus Christi, Texas 78412-5837, USA.

***TRACHEMYS SCRIPTA ELEGANS* (Red-eared Slider)**. USA: WISCONSIN: Kenosha Co.: unnamed tributary of Des Plaines River on west side of Interstate 94 and north side of County Hwy C (93rd St.), T1N R21E Section 13 SE1/4 (42.545747°N, 87.955437°W; WGS84). 18 June 2009. Gary S. Casper, Thomas G. Anton. Verified by Alan Resetar. FMNH 281241. First reproductive record for the state (Casper 1996. Geographic Distributions of the Amphibians and Reptiles of Wisconsin. Milwaukee Public Museum, 87 pp.). A gravid adult female trapped in a baited hoop net.

Red-eared Sliders are occasionally reported from urban ponds and nature centers in Madison and Milwaukee, disjunct from the known natural range, and are presumed to be released pets (Bob Hay, Wisconsin DNR, pers. comm.). This gravid female represents the first Wisconsin record from a stream system within the natural range (Phillips et al. 1999. Field Guide to Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Man. 8, Champaign, Illinois. 282 pp.), and is considered a natural occurrence in an industrial corridor without public access (as is typical of release sites). Recent (post-1985) records are available from the Des Plains River watershed in Cook (FMNH 267587, INHS 16868), DuPage (INHS 10775), and Will (FMNH 251323) counties, Illinois. A specimen was also collected in 1876 from Lake County, Illinois (FLMNH 51108). The eventual establishment of sliders in Wisconsin has been predicted, possibly abetted by ongoing climate warming (Casper 2008. Bull. Chicago Herpetol. Soc. 43[5]:73–79). Regardless of origin, sliders are now breeding in Kenosha Co., and should be added to the state herpetofaunal list.

Dissertação apresenta do Programa de Pós-graduação em Zoologia, Museu Paraense Emílio Goeldi e Universidade Federal do Pará, 53 pp.; Ribeiro-Júnior 2006. S. Am. J. Herpetol. 1[2]:131–137; Macedo et al. 2008. Biota Neotrop. 8[1]:133–139; Freire 1996. Rev. Bras. Zool. 13[4]:903–921; Moraes 2008. Diversidade beta em comunidades de lagartos em duas ecorregiões distintas na Amazônia. Dissertação apresentada ao Programa de Pós-graduação em Biologia Tropical e Recursos Naturais, 40 pp.). First state record, partially filling the gap between Paraíba and Alagoas states; the locality is 100 km S from Cabedelo, Paraíba, and 160 km N from Ibateguara, Alagoas.

MARIANA MIRANDA D'ASSUNÇÃO, DANILO SÁ BARRETO BARROS FILHO, ARMANDO DOS SANTOS ARAÚJO, and **GERALDO JORGE BARBOSA DE MOURA**, Universidade Federal Rural de Pernambuco, Paleoherpetological and Herpetological Laboratory, UFRPE, Rua Dom Manoel de Medeiros, Dois Irmãos - CEP: 52171-900, Recife, PE, Brazil.

***ANOLIS SAGREI* (Brown Anole)**. USA: GEORGIA: McIntosh Co.: Darien, GA Hwy 251, 0.6 km NW of I-95 (31.399967°N, 81.453167°W; WGS 84). 07 May 2009. Georgia Museum of Natural History (GMNH) 50126. First county record. Adult male collected from hotel landscaping and several dozen adults observed on hotel grounds and the edges of adjacent wooded areas. Hotel manager stated that *A. sagrei* were present throughout his two-year tenure. Adult female (GMNH 50127) collected during a subsequent visit on 08 June 2009, at which time several individuals were also observed in the parking lot landscaping of a nearby outlet mall.

Liberty Co.: near Midway, US-84, 0.5 km NW of I-95 (31.781033°N, 81.383250°W; WGS 84). 08 June 2009. GMNH 50128. First county record. Adult female collected from vegetation bordering a parking lot; three additional adult females observed in overgrown vegetation along the parking lot edge.

Brian Co.: Richmond Hill, US-17, 0.2 km E I-95 (31.928017°N, 81.327933°W). 08 June 2009. GMNH 50129. First county record. Adult male collected from fencerow vegetation aside a motel parking lot. Three additional adult males and two adult females observed in a 15-minute search of the motel grounds.

Chatham Co.: Port Wentworth, GA Hwy 21, 0.6 km NW I-95 (32.197267°N, 81.195617°W). 08 June 2009. GMNH 50130. First county record. Adult male collected and two adult females observed in hotel landscaping. Several additional lizards, likely *A. sagrei*, heard moving within dense shrubs. All specimens collected by N. W. Turnbough and verified by A. C. Echternacht.

These records fill a distributional gap between Glynn Co. in southeast Georgia (Campbell 1996. Herpetol. Rev. 27:155–157) and Jasper Co., South Carolina (Turnbough 2006. Herpetol. Rev. 37:361). They resulted from an attempt by the author to assess *A. sagrei* dispersal into the region via vehicular rafting (Godley et al. 1981. Herpetol. Rev. 12:84-86; Campbell 1996, *op. cit.*). An I-95 exit was selected for each county and a suitable site for searching was identified upon exiting—hotels/motels or truck stops with adequate landscaping or surrounding vegetation. *Anolis sagrei* were discovered with a single attempt for each county except Chatham, where the second attempt was successful. Such ease in finding *A. sagrei* suggests that the species was likely widespread throughout the I-95 corridor in Georgia, at least in exit areas, prior to the particularly severe winters of 2009/10 and 2010/11. Vehicular rafting appears to be the most parsimonious explanation for *A. sagrei* dispersal to all of the above sites, though transport in nursery plants may be a possibility for the hotel/motel sites.

South Carolina: Concurrent with or prior to the above collection efforts, the establishment of *A. sagrei* in previously reported South Carolina rest area localities (Turnbough 2006, *op. cit.*) was investigated. The Jasper Co. site was visited every year from 2006–2009, and in those years an established *A. sagrei* population spread throughout the site and became increasingly abundant. The Colleton Co. and Orangeburg Co. sites were each searched for approximately 15 minutes on 08 June 2009: three adult males and one adult female were observed in vegetation surrounding the Colleton Co. rest area facilities, and seven adult males and one adult female were observed around the Orangeburg Co. facilities. Because overwinter survival is probably the limiting factor for *A. sagrei* establishment in South Carolina, the increased abundance of *A. sagrei* at these two localities likely signified population establishment rather than higher rates of post-winter vehicular disembarkation. All of the reported South Carolina populations may have been extirpated by the unusually cold winter of 2010/11, however, as *A. sagrei* were not found in four searches of the sites by up to three observers in summer 2011 (L. Rubio-Rocha, pers. comm.). Notably, *A. carolinensis*, which was present at the Jasper Co. site and abundant at the other two sites in 2009, was still present at all three sites in summer 2011.

JEAN-FRANÇOIS TRAPE, Institut de Recherche pour le Développement, B.P. 1386, Dakar, Senegal (e-mail: jean-francois.trape@ird.fr); and **IVAN INEICH**, Muséum national d'Histoire naturelle, Département de Systématique et Evolution, CNRS UMR 7205 (Origine, Structure et Evolution de la Biodiversité), CP 30, 25 rue Cuvier, 75231 Paris Cedex 05, France.

***PHRYNOSOMA MODESTUM* (Round-tailed Horned Lizard)**. USA: OKLAHOMA: Le Flore Co. 1940. W. C. Hobgood. Verified by Alan Resetar. FMNH 40808 (accessed through the HerpNet2 Portal, www.herpnet2.org, 26 Sep. 2011). This specimen was originally identified as *P. cornutum*, and was only recently corrected. The record represents a geographic range extension of approximately 550 km from the nearest confirmed county record of *P. modestum* in Hall Co., Texas (Dixon 2000. Amphibians and Reptiles of Texas. Texas A&M University Press, College Station. 500 pp.), excluding an unconfirmed Baylor Co. account that was considered erroneous (Axtell 1988. Interpretive Atlas of Texas Lizards [6]:1–18 + map. Southern Illinois University, Edwardsville).

The closest confirmed location of *P. modestum* in Oklahoma is approximately 790 km distant, in Cimarron Co. (Clarke 1983. Bull. Oklahoma Herpetol. Soc. 12:16). Museum records indicate that FMNH 40808 was collected in Le Flore Co., Oklahoma near Rich Mountain, Arkansas; we suggest this means the specimen was taken in Le Flore Co., Oklahoma very close to the Arkansas border adjacent to Rich Mountain, Arkansas. No additional locality information is available. There is apparently a peripheral population of *Crotalus atrox* in the Ouachita Mountains, another species with a more southwestern U.S. primary distribution (Sievert and Sievert 2011. A Field Guide to Oklahoma's Amphibians and Reptiles. Oklahoma Dept. Wildlife Conservation, Oklahoma City. 211 pp.). Future surveys for *P. modestum* in the area should be conducted to determine if the species persists in eastern Oklahoma.

LEAVITT,** MS 2258, Texas Cooperative Wildlife Collection, Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, Texas 77843, USA (e-mail: dlea886@tamu.edu).

***PLESTIODON LATICEPS* (Broad-headed Skink)**. USA: OHIO: Lawrence Co.: Symmes Township, Wayne National Forest (38.76625°N, 82.53390°W; WGS 84). 5 June 2010. B. Folt and C. Brune. Verified by Scott Moody. Photo voucher in Cincinnati Museum Center, Geier Collections and Research Center (CMC HP 6543). New county record (Wynn and Moody 2006. Ohio Turtle, Lizard, and Snake Atlas. Ohio Biol. Surv. Misc. Contr. No. 10, Columbus. iv + 81 pp.).

BRIAN P. FOLT, Department of Biological Sciences, Auburn University, Auburn, Alabama 36849-5414, USA; e-mail: brian.folt@gmail.com.

***POLYCHRUS MARMORATUS* (Green Lizard)**. BRAZIL: ALAGOAS: Municipality of Maceió: Serra da Saudinha (09.366°S, 35.750°W; SAD69). November 2005. U. Gonçalves and S.

Torquato. Setor de Zoologia, Coleção Herpetológica do Museu de História Natural, Universidade Federal de Alagoas, Brazil (MUFAL 3542; collecting license IBAMA/RAN 184/05). Verified by G. Skuk. Municipality of Campo Alegre: Fazenda Pindoba (09.758889°S, 36.235833°W; SAD69; elev. 121 m). 17 April 2007. I. C. S. Tiburcio and others. Museu de Zoologia da Universidade de São Paulo, São Paulo, Brazil (MZUSP 98144; collecting license IBAMA/RAN 204/06). Verified by H. Zaher. The species was previously recorded from rainforests of Guiana Francesa, Suriname, Guiana, Venezuela, Colômbia, Equador, Peru, and Brazil (Ávila-Pires 1995. Zool. Verh. 1–706). In Brazil the species was mentioned from Amazonas, Amapá, Maranhão, Pará, Roraima, Rondônia, Mato Grosso Ceará, Paraíba, Pernambuco, Bahia, Espírito Santo, and São Paulo (Vanzolini 1974. Pap. Avul. Zool. 18[4]:61–90; Vanzolini 1983. *In* Rhodin and Miyata [eds.], Advances in Herpetology and Evolutionary Biology: Essays in Honor of Ernest E. Williams, pp. 118–131. Museum of Comparative Zoology, Cambridge, Massachusetts; Ávila-Pires 1995, *op. cit.*; Kawashita-Ribeiro and Ávila 2008. Check List 4[3]:362–365; Santana et al. 2008. Biotemas 21[1]:75–84; Turci and Bernarde 2008. Bioikos 22[2]:101–108; Silva-Soares et al. 2011. Check List 7[3]:290–298). First state records, the localities (Serra da Saudinha and Fazenda Pindoba) are about 214 km and 268 km south of nearest occurrences, respectively (municipality of Timbaúba, state of Pernambuco).

JOSÉ VIEIRA DE ARAÚJO-NETO (e-mail: netovieiraaraujo@gmail.com), **INGRID CAROLLINE SOARES TIBURCIO, JÉSSICA YARA ARAUJO GALDINO, UBIRATAN GONÇALVES,** and **SELMA TORQUATO DA SILVA,** Setor de Zoologia, Museu de História Natural, Universidade Federal de Alagoas, Av. Aristeu de Andrade, 452, Farol, CEP: 57021-090, Maceió, Alagoas, Brazil.

***SCELOPORUS TRISTICHUS* (Plateau Fence Lizard)**. USA: WYOMING: Natrona Co.: near Muddy Mountain Educational Center, on the southern slope of Casper Mountain in a small canyon north of County Road 505 (42.707490°N, 106.396642°W; WGS 84). 29 June 2011. K. J. Weber and K. P. Leuenberger. Verified by Adam Leache. INHS 2011o. New county record (Baxter and Stone 1985. Amphibians and Reptiles of Wyoming. 2nd ed. Wyoming Game and Fish Department, Cheyenne. 137 pp.).

One individual (male) was observed at this site. Subsequently an adult female was captured and observed (42.65369°N, 106.35277°W) on 27 July 2011. Four more individuals were captured near Casper, 20 km E (42.699509°N, 106.142660°W) on 30 June 2011. *S. tristichus* is known to occur in Albany, Laramie, Platte, and Converse counties where it exclusively inhabits rocky outcrops and crevices (Baxter and Stone, *op. cit.*). These observations extend the range of *S. tristichus* approximately 30 km.

KATHERINE J. WEBER (e-mail: kjweber@eiu.edu) and **KATHERINE P. LEUENBERGER,** Aquatic Assessment Crew, Wyoming Game and Fish Department, 3030 Energy Lane, Casper, Wyoming 82604, USA (e-mail: Katie.Leuenberger@wyo.gov).

***TARENTOLA PARVICARINATA* (White-spotted Wall Gecko)**. MOROCCO: WESTERN SAHARA: Ca. 10 km NW Galtat Zemmour (25.218°N, 12.445°W; WGS 84; 465 m elev.). 1 October 2006. J.-F. Trape. Institut de Recherche pour le Développement at Dakar (IRD TR.1804). Verified by Philippe Geniez. First record for Morocco (Western Sahara), extends known range ca 400 km N of Adrar mountains in Mauritania (Geniez et al. 2006. The Amphibians and Reptiles of the Western Sahara. Edition Chimaira, Frankfurt an Main, 228 pp.; Padial 2006. Graellsia 62:159–178).

JEAN-FRANÇOIS TRAPE, Institut de Recherche pour le Développement, B.P. 1386, Dakar, Senegal (e-mail: jean-francois.trape@ird.fr).

***TROPIOCOLOTES TRIPOLITANUS* (Tripoli Pigmy Gecko)**. CHAD: KANEM REGION: Ca. 4 km W of Méchiméré (13.832°N, 15.769°E; WGS 84; 285 m elev.). Two specimens collected at night on sandy area near roots of *Acacia* trees. 16 January 2003. J.-F. Trape. Institut de Recherche pour le Développement at Dakar (IRD TR.02 and TR.04). Verified by Laurent Chirio. First records for Chad (Sindaco and Jeremcenko 2008. The Reptiles of the Western Palearctic. Edizioni Belvedere, Latina. 579 pp.; Uetz and Hošek 2011. The Reptile Database. http://www.reptile-database.org/. Accessed December 2011).

JEAN-FRANÇOIS TRAPE, Institut de Recherche pour le Développement, B.P. 1386, Dakar, Senegal (e-mail: jean-francois.trape@ird.fr).

***VARANUS DUMERILII* (Dumeril's Monitor)**. INDONESIA: SUMATERA SELATAN PROVINCE: Musi Banyuasin District: eastern lowlands of Sumatra, along border with Jambi Province (1.8186°S, 104.1206°E, Google Earth; 35 m elev.). 12 October 1995. Mark R. Bezuijen. Verified by Mark Auliya. Photographic voucher deposited in the Zoological Reference Collection of the Raffles Museum of Biodiversity Research, National University of Singapore (ZRC[IMG] 2.159). Adult, observed at 1100 h, motionless among sedges, *Pandanus* and felled timber on swampy ground, in large tract of selectively logged lowland dipterocarp forest with numerous small creeks (tree genera including *Shorea*, *Anisopthera*, *Gonostylus*; understory 5–10 m, canopy 25–30 m). Identified on basis of dark brown-black dorsum with dull yellow transverse bands; large nuchal scales, not arranged in longitudinal rows; large, oval and keeled dorsal scales; and tail laterally compressed with strong double keel (de Rooij 1915. The Reptiles of the Indo-Australian Archipelago. I. Lacertilia, Chelonia, Emydosauria. E. J. Brill Ltd, Leiden. xiv + 384 pp.). Widely distributed in Southeast Asia, but with few published locality records; some specimens mistaken for *V. rudicollis* (Bennett and Lim 1995. Malayan Nat. J. 49:113–116; Böhme 2003. Zool. Verh. 341:3–43; Bennett 2004. *In* Pianka et al. [eds.]. Varanoid Lizards of the World, pp. 172–175. Indiana University Press, Bloomington; Cota et al. 2008. Biawak 2:152–158). Previously recorded from eastern Sumatra (de Rooij 1915, *op. cit.*), although the provenance of some records is unclear.

MARK R. BEZUIJEN, P.O. Box 183, Ferny Creek, Victoria, Australia 3786; e-mail: bezuijen@dodo.com.au.

MÉXICO: OAXACA: Municipality of San Pedro Mixtepec: Jardín Botánico Puerto Escondido de la Universidad del Mar (JBPE UMAR), km 239 on Sola de Vega-Puerto Escondido Road, ca. 6 km N of Puerto Escondido (15.916947°N, 97.076694°W; WGS 84), 88 m elev. 28 January 2008. Guillermo Sanchez-de la Vega. Verified by Jerry D. Johnson. Laboratorio de Colecciones Biológicas, Universidad del Mar, Campus Puerto Escondido (Rep-42). First municipality record that fills a gap between the nearest confirmed localities, ca. 216 km WNW in Copala, Guerrero (Armstrong and Murphy 1979. Spec. Publ. Mus. Nat. Hist., Univ. Kansas [5]:i–vii, 1–88) and ca. 175 km ENE between Salina Cruz and Tequisistlán on the Isthmus of Tehuantepec (Gadow 1908. Through Southern México. Whitherby and Co., London. xvi + 257 pp.). Gloyd (1940. Spec. Publ. Chicago Acad. Sci. [4]:i–viii, 1–270) shows a map depicting a locality further west (possibly near Puerto Angel?) to the one reported by Gadow (1940, *op. cit.*), but he failed to include it in the localities he listed for Oaxaca. The same locality was seemingly mapped by Campbell and Lamar (2004. The Venomous Reptiles of the Western Hemisphere, Vol. II. Comstock Publ. Assoc., Ithaca, New York. xiv + 477–870 pp.). The adult female was DOR near the main entrance to JBPE UMAR. The vegetation in the area is represented primarily by tropical deciduous forest.

***DIADOPHIS PUNCTATUS ARNYI* (Prairie Ring-necked Snake)**. USA: NEBRASKA: Harlan Co.: approx. 1.5 mi. NNE Alma (39.85907°N, 93.60844°W; elev. 624 m). 23 May 2011. Brian Hubbs. Verified by Dan Fogell. Natural History Museum of Los Angeles County photo voucher LACM PC 1562. New county record (Ballinger et al. 2010. Amphibians and Reptiles of Nebraska. Rusty Lizard Press, Oro Valley, Arizona. 400 pp.; Fogell 2010. The

Amphibians and Reptiles of Nebraska. University of Nebraska Press, Lincoln, Nebraska. 158 pp.).

BRIAN HUBBS, PO Box 26407, Tempe, Arizona 85285, USA; e-mail: tricolorbrian@hotmail.com.

***HETERODON PLATIRHINOS* (Eastern Hognose Snake).** USA: TENNESSEE: McNairy Co.: Finger, 294 Sherry Lynn Drive (35.357800°N, 88.635583°W; WGS84). 4 October 2011. Brian P. Butterfield. Verified by A. F. Scott. Austin Peay State University (APSU 19168 photographic voucher). New county record (Scott and Redmond 2008 [latest update: 8 November 2011]. Atlas of Reptiles in Tennessee. Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. Available at http://apsu.edu/reptatlas/, accessed 9 November 2011). Juvenile male found in a residential garage located in a rural subdivision within an oak-hickory forest.

BRIAN P. BUTTERFIELD, Department of Biology, Freed-Hardeman University, Henderson, Tennessee 38340, USA; e-mail: bbutterfield@fhu.edu.

***HYPSIGLENA CHLOROPHAEA DESERTICOLA* (Northern Desert Nightsnake).** USA: UTAH: Cache Co.: River Trail at Stokes Nature Center, south side, Logan Canyon (41.741938°N, 111.768623°W; WGS 84). 13 August 2011. A. M. Durso, K. P. Durso, N. M. Kiriazis, L. A. Neuman-Lee. Verified by Jack W. Sites, Jr. BYU 49957. Found crossing a dirt path at 2139 h. A second specimen (BYU 49958) was found in Logan Canyon.

These two records confirm the presence of *H. chlorophaea* in Cache Co. (Cox and Tanner 1995. Snakes of Utah. Bean Life Science Museum, Provo, Utah. 92 pp.), where it had not been recorded until recently (Mulcahy 2008. Mol. Phylog. Evol. 46:1095–1115), and expands the range of known localities within the county (B. Sutter, Utah Natural Heritage Database, pers. comm.). In October 2005, a single voucher specimen (CAS 235907) was collected in River Heights by a grade school student. Anecdotal reports exist for additional River Heights records (J. A. MacMahon, pers. comm.). Together, these three specimens fill a gap between the nearest records, from ca. 67 mi (airline) S at Fort Douglas, Salt Lake Co., Utah (CAS 30925, 30926) and ca. 81 mi (airline) NE at ~ 1 mi SE of Pocatello, Bannock Co., Idaho (Linder and Fichter 1977. Amphibians and Reptiles of Idaho. Idaho State Univ. Press, Pocatello. 78 pp.).

***RHABDOPHIS HIMALAYANUS* (Himalayan Keelback)**. BANGLADESH: SYLHET DIVISION: Moulovibazaar District: Lawachara National Park (24.330963°N, 91.801120°E; WGS 84; ca. 50 m asl.). Three roadkilled individuals were also found on former Dhaka-Sylhet highway, dissecting Lawachara National Park. 8 July 2011. Verified by Gernot Vogel. Photographic voucher, Raffles Museum of Biodiversity Research, National University of Singapore (ZRC [IMG] 2.154). First confirmed locality record from Bangladesh. Khan (2008. Protected Areas of Bangladesh- A Guide to Wildlife. Nishorgo Program, Bangladesh Forest Department, Dhaka, Bangladesh. 304 pp.) mentioned of a record in northwest Bangladesh, but without locality information, voucher specimen or photographs. Nearest populations recorded from Assam, Meghalaya, northern Bengal and Sikkim, in India (Ahmed at al. 2009. Amphibians and Reptiles of Northeast India. A Photographic Guide. Aaranyak, Guwhati. 168 pp.) Four live individuals found in mixed plantation forest.

SHAHRIAR CAESAR RAHMAN, Department of Environmental Science, Independent University, Dhaka, Bangladesh (e-mail: caesar_rahman2004@yahoo.com); **MUSHFIQ AHMED**, Prokriti o Jibon Foundation, Dhaka, Bangladesh (e-mail: mushfiq.ahmed@yahoo.com).

***RHADINAEA FLAVILATA* (Pine Woods Littersnake)**. USA: GEORGIA: Camden Co.: Cumberland Island (30.8153°N, 81.46956°W; WGS 84) 31 May 2011. C. Ruckdeschel. Verified by C. K. Dodd and K. Krysko. Florida Museum of Natural History (photo voucher UF 165513). New island record (Jensen et al. [eds.] 2008. Amphibians and Reptiles of Georgia. Univ. of Georgia Press, Athens. 575 pp.). Single adult in damp area.

C. RUCKDESCHEL, Cumberland Island Museum, P.O. Box 7080, St. Marys, Georgia 31558, USA; e-mail: cimuseum@yahoo.com.

***RHADINAEA LAUREATA* (Crowned Graceful Brownsnake)**. MÉXICO: CHIHUAHUA: Municipio de Bocoyna: near km 86 on Hwy 25 N of Creel (27.789694°N, 107.651972°W; NAD27), 2355 m elev. 12 July 2008. Robert W. Bryson, Jr. and Mike Torocco. UAZ 57331-PSV. Municipio de Guadalupe y Calvo, approximately 1 km N of Baborigame (26.425975°N, 107.268522°W; NAD27), 1800 m elev. 10 October 2008. Ricardo Ramírez-Chaparro and Jesús Enrique-Fuentes. UAZ 57321-PSV. Both specimens verified by Irene Goyenechea and Charles W. Myers. The two localities are separated by ca. 154 km and are the first records for Chihuahua, representing range extensions of 360 km northwest and 312 km northwest, respectively, from the closest recognized records at Laguna del Progresso, Durango (UMMZ 113625–113627; Myers 1974. Bull. Am. Mus. Nat. Hist. 153:1–262); UAZ 57331-PSV is also the northernmost record for this species in Mexico. Both snakes were found in pine-oak woodlands on the Sierra Madre Occidental.

BRIAN HUBBS, PO Box 26407, Tempe, Arizona 85285, USA; e-mail: tricolorbrian@hotmail.com.

***THAMNOPHIS SAURITUS SAURITUS* (Common Ribbonsnake)**. USA: ALABAMA: Sumter Co.: Near a wet seep on a Selma Chalk exposure (32.98652°N, 88.21576°W; WGS84/NAD83). 18 October 2011. R. Birkhead. Verified by Craig Guyer. AUM 39703. New county record. *T. s. sauritus* is assumed to occur statewide, however verified records are lacking for some counties (Mount 1996. The Reptiles and Amphibians of Alabama. University of Alabama Press, Tuscaloosa. xi + 347 pp.).

ROGER D. BIRKHEAD, Alabama Science In Motion, Auburn University, Alabama 36849-5414, USA; e-mail: birkhrd@auburn.edu.

***TROPIDOCLONION LINEATUM* (Lined Snake)**. USA: WISCONSIN: Iowa Co.: specific locality information withheld due to the sensitive nature of the site. C. Raimond and J. M. Lorch. Verified by Joshua Kapfer and Rori Paloski. Illinois Natural History Survey (INHS 2011m photo voucher). New state record. Extends the known range of this species by approximately 95 km (Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Books, 668 pp.; INHS 21335 from Jo Daviess Co., Illinois). Two adults were observed on a dry prairie remnant on 4 September 2011; an additional adult (based on differences in belly pattern) was located on 10 September 2011. The site lies within an historic prairie complex (Curtis 1959. The Vegetation of Wisconsin: An Ordination of Plant Communities. University of Wisconsin Press, Madison. 640 pp.) that is now a mixture of pastureland, active agricultural fields, and scattered prairie remnants. The main range of *Tropidoclonion lineatum* extends from southeastern South Dakota south to the Gulf Coast of Texas, but there are isolated populations in northern and central Illinois, southeastern Iowa, east-central Missouri, eastern Colorado, and New Mexico (Ernst and Ernst 2003, *op. cit.*). The nearest known population to the Wisconsin site occurs in southern Jo Daviess Co., Illinois (Bowen 2004. Herpetol. Rev. 35:413). It is unclear whether the Wisconsin animals represent a population disjunct from that of northwest Illinois or whether the secretive habits of this semi-fossorial snake are responsible for the paucity of records. Habitat similar to that found at the newly discovered site is present throughout large portions of Grant, Green, Lafayette, and Iowa counties, Wisconsin, and the species might be more widely distributed in the state than this one record indicates.

COREY RAIMOND, 1713 Camus Lane, Madison, Wisconsin 53705, USA; **JEFFREY M. LORCH,** Molecular and Environmental Toxicology Center, University of Wisconsin-Madison, 1300 University Avenue, Wisconsin 53706, USA.

***VIRGINIA STRIATULA* (Rough Earthsnake)**. USA: ARKANSAS: Sevier Co.: 5.1 km E of King off Co. Rd. 342 (34.144665°N, 94.238405°W; WGS 84). H. W. Robison. Verified by S. E. Trauth. Arkansas State University Museum of Zoology Herpetological Museum (ASUMZ 31903). New county record filling a distributional hiatus in extreme southwestern Arkansas near previous record in Miller Co. (Trauth et al. 2004. Amphibians and Reptiles of Arkansas. Univ. Arkansas Press, Fayetteville. 421 pp.).

CHRIS T. McALLISTER, Science and Mathematics Division, Eastern Oklahoma State College, 2805 NE Lincoln Road, Idabel, Oklahoma 74745, USA (e-mail: cmcallister@se.edu); **HENRY W. ROBISON**, Department of Biology, Southern Arkansas University, Magnolia, Arkansas 71754, USA (e-mail: hwrobison@yahoo.com).

***VIRGINIA VALERIAE* (Smooth Earthsnake)**. USA: OHIO: Gallia Co.: Greenfield Township, Dry Ridge Road (Township Hwy 596) in the Wayne National Forest (38.78122°N, 82.54766°W; WGS 84). 5 June 2010. B. Folt and C. Brune. Verified by Scott Moody. Cincinnati Museum Center, Geier Collections and Research Center (CMC HP 6550 photo voucher). New county record (Wynn and Moody 2006. Ohio Turtle, Lizard, and Snake Atlas. Ohio Biol. Surv. Misc. Contr. No. 10, Columbus. iv + 81 pp.).

New Distributional Records from the Lesser Sundas, Indonesia

The Lesser Sunda islands stretch from 114.43° to 127.37°E and lie between latitudes of 8 and 10°S. The islands are primarily volcanic in origin, and currently experience a tropical seasonally wet-dry climate which in general becomes increasingly xeric towards the east, and correspondingly, supports vegetation communities ranging from rainforest to grasslands. The associated herpetofauna is also greatly influenced by altitude and isolation, in addition to being an area of integration between faunas of Asian and Australopapuan origins, the much-discussed zone of Wallacea. Consideration of this zone, and biodiversity of the Lesser Sundas otherwise, has been intrinsically hampered by incomplete zoogeographical knowledge. Of the islands, the two best known are Komodo and Bali, with studies of 17 months (Auffenberg 1980) and nine months (McKay 2006), respectively. Both studies increased the known faunal content considerably, 25% in the case of Bali. Information for the rest of the archipelago is comparatively thinner, despite the efforts of various researchers over the course of the last one hundred years. Recent publications, de Lang's (2011) synthesis of the snakes and the results of the Western Australian Museum/Museum Zoologicum Bogoriense expeditions conducted during 1987–1993 (e.g., How et al. 1996a, 1996b; 1998; How and Kitchener 1997), provide the most modern overview of the herpetofauna, and supported by Merten's works during early to mid-1900s (e.g., Mertens 1927a; 1927b; 1928; 1957), other species-specific or taxonomic snippets (e.g., Das 1993; Iskandar et al.1996; Wüster 1996), and the baseline data of seminal publications, such as de Rooij (1915; 1917), Boulenger (1897) and van Kampen (1923), this forms the body of our herpeto-zoogeographical knowledge for the Lesser Sundas.

From 2007 to 2011, we visited the Lesser Sundas, one of us was resident on Bali (RL), and in combination spent approximately 50 months on Bali, four months on Lombok, one month on Sumbawa, and one month on Flores. For islands other than Bali, field work was conducted mainly between October and March, the hottest and wettest time, employing searches on foot or from vehicle, and at a few locations (e.g., Sape, Sumbawa) the aid of local snake handlers. Locations were recorded with GPS in the datum WGS84; digital photographs as vouchers were lodged in the collection of the Museum of the Northern Territory, Australia (NTM). Here, we present the resulting new distributional records, again clearly demonstrating that the herpetofaunal composition of these islands remains incomplete, even those as well known as Bali. The use of traps, which in this case was not available to us, would undoubtedly yield further interesting results. In terms of conservation, viewing these islands as more biodiverse than we realize evinces the value of utilizing widespread societal change (i.e., changing attitudes and practices towards preserving natural ecosystems, vegetation or organisms), as equal in importance to the scattering of formally protected areas in Indonesia.

ANURA — FROGS

***DUTTAPHRYNUS MELANOSTICTUS* (Asian Eyebrow-ridge Toad)**. SUMBAWA: Sekongkang (8.9653°S, 116.7526°E). 10 Feb 2010. Dompu (8.5356°S, 118.4671°E).13 Feb 2010. NTM 05113Dmel. Sape (8.5744°S, 119.0082°E). 14 Feb 2011. Common and often breeding. In the Lesser Sundas, known from Bali, Lombok and Timor (McKay 2007). Notably, not yet recorded from Komodo or Flores.

SQUAMATA — LIZARDS

***CYRTODACTYLUS DARMANDVILLEI* (D'Armandville's Forest Gecko)**. LOMBOK: Kuta (8.9069°S, 116.3067°E). 14 Oct 2007. NTM 1007CrytoSpX. Common in rock outcrops. Previously known from Sumbawa and islands further east (Mertens 1930). First record for Lombok.

FIG. 1. *Lepidodactylus intermedius*, Flores, Lesser Sunda islands. First published photograph of a living example.

PHOTO BY J. L. MCKAY

FIG. 2. *Typhlops schmutzi*, Sumbawa, Lesser Sunda islands. First published photograph of a living specimen.

***HEMIDACTYLUS GARNOTII* (Fox Gecko)**. FLORES: Ruteng (8.6160°S, 120.4640°E). 18 Jan 2011. NTM 04343Hgar. Common on unlit walls in town. A widespread species, known from Lombok (Mertens 1927b), but apparently the first record from the eastern Lesser Sundas.

***LEPIDODACTYLUS INTERMEDIUS* (Komodo Mourning Gecko)**. FLORES: Reo (8.3071°S, 120.4997°E). 20 Jan 2011. NTM 04493Lint. One adult on mango tree in suburban situation (Fig. 1). Ota et al. (2000) distinguish preserved specimens of this species from preserved *L. lombocensis* by the extent of interdigital webbing and dorsal pattern. Examination of the dorsum of live specimens of both species (see also below) shows them to be highly similar. First record from the Flores mainland, otherwise known from the smaller islands of Komodo and Rinca (Auffenberg 1980).

***LEPIDODACTYLUS LOMBOCENSIS* (Lombok Mourning Gecko)**. BALI: Ubud (8.5096°S, 115.2619°E). 10 June 2010. NTM 02089Llom. One adult found climbing a divider outside a hotel room. Previously known from Lombok (Ota et al. 2000).

***CRYPTOBLEPHARUS RENSCHI* (Blue-tailed Snake-eyed Skink)**. FLORES: Labuan Bajo (8.4861°S, 119.8789°E). 10 Jan 2011. NTM 04175Cren. Pulau Seraya Kecil (8.4129°S, 119.8698°E). 3 March 2011. A common arboreal lizard. Auffenberg (1980) believed this taxon to exist on Flores on the basis of a personal sighting, although no specimens or records existed, and here, we confirm its presence on Flores. The species has a disjunct distribution occurring in the Kangean islands north of Java, parts of Bali, Komodo, Rinca, Longo, and Sumba.

***EMOIA ATROCOSTATA ATROCOSTATA* (Mangrove Skink)**. BALI: Gilimanuk (8.1757°S, 114.4408°E). 16 Nov 2007. NTM 1107EatroA. One adult in mangrove dominated by *Rhizophora* sp. LOMBOK: Gili Sulat (8.3230°S, 116.7107°E). 26 Jan 2010. One adult in mangrove dominated by *Rhizophora* sp. Kuta (8.9069°S, 116.3067°E). 3 Feb 2010. One adult on a beach with conglomerate boulders. SUMBAWA: Karumbu (8.7041°S, 118.8090°E). 16 Feb 2011. Three adults inhabiting small rocks on mudflat. Although ranging widely in Indonesia (Brown 1991), occurrence of populations is patchy, and these are the first specific records for these islands.

***EMOIA KITCHENERI* (Kitchener's Emoia)**. FLORES: Aimere (8.8380°S, 120.8531°E). 26 Jan 2011. NTM 04462Ekit. One adult climbing low on a banana plant in riparian situation. First record for Flores, previously only the type series from the vicinity of Ngallu, Sumba were known (How et al. 1998).

***EMOIA SIMILIS* (Dunn's Emoia)**. FLORES: Labuan Bajo (8.4861°S, 119.8789°E). 9 Jan 2011. NTM 04148Esim. One adult in savannah. How et al. (1998) mention *Emoia similis* from the opposite end of Flores (Larantuka) have colouration sufficiently different from the type to warrant taxonomic investigation. Brown (1991) includes Flores in the species' distribution without further details. Here, we confirm its presence on western Flores, from a specimen which agreed closely in appearance with the typical form known from neighboring Komodo and Rinca (Auffenberg 1980).

***LAMPROLEPIS SMARAGDINA* (Emerald Tree Skink)**. SUMBAWA: Pantai Lakey (8.8039°S, 118.3836°E). 28 Feb 2011. NTM 05102Lsma. Common in monsoon forest and on coconut palms of foreshore. Known previously from Lombok and Flores (Mertens 1930); notably, still unknown from Komodo (Auffenberg 1980).

***LYGOSOMA BOWRINGII* (Bowring's Supple Skink)**. FLORES: Labuan Bajo (8.4861°S, 119.8789°E). 9 Jan 2011. NTM 04167Lbow. Reo (8.3071°S, 120.4997°E). 21 Jan 2011. Adults taken in monsoon forest. First records for Flores. Previously known from Lombok (Mertens 1927b), Nusa Penida (McKay 2006), and areas further west.

***SPHENOMORPHUS SCHLEGELI* (Schlegel's Forest Skink)**. FLORES: Labuan Bajo (8.4861°S, 119.8789°E). 12 Jan 2011. NTM 04245Ssc. Near Reo (8.3071°S, 120.4997°E). 23 Jan 2011. Adults taken in monsoon forest. First records for Flores, previously considered endemic to Komodo and Rinca (Auffenberg 1980).

SQUAMATA — SNAKES

***TYPHLOPS SCHMUTZI* (Reverend Schmutz's Blind Snake)**. SUMBAWA: Sumi (8.6035°S, 119.0155°E). 15 Feb 2011. NTM 04931Tsch. One adult taken in a deep leaf litter bed at the base of a limestone outcrop in closely vegetated situation (Fig. 2). Previously known from Komodo and Flores (Auffenberg 1980), this is the first record for Sumbawa.

***BOIGA DENDROPHILA DENDROPHILA* (Mangrove Snake)**. BALI: Silakarang (8.5944°S, 115.2564°E). 18 Sep 2010 and 20 Sep 2010. NTM 3RL. One dead animal found floating in a stream, and two adults photographed sitting together in a coconut palm, ca. 20 m above ground. Previously known from Java, and further west.

***CALLIOPHIS INTESTINALIS INTESTINALIS* (Asian Coral Snake)**. BALI: Mas (8.5428°S, 115.2761°E). 23 Jan 2011. NTM 1 RL/NTM 4 RL. One specimen discovered during excavation work for a pool. Previously known from Java and further west.

***DABOIA SIAMENSIS* (Eastern Russell's Viper)**. SUMBAWA: Sumi (8.6035°S, 119.0155°E). 18 Feb 2011. NTM 04958Dsi. One adult in savannah. Ca. 15 km N of Bima (8.4145°S, 118.7730°E). 21 Feb 2011. Roadkill adult from highly transformed open shrubland. Sape (8.5744°S, 119.0082°E), without exact locality. Two adults collected in the vicinity by local snake handler. First records from Sumbawa; other Lesser Sunda populations occur sporadically eastwards to Lomblen (de Lang 2011).

Acknowledgments.—We thank Junai Dae Sira of Sape, Sumbawa, for providing specimens of *Daboia siamensis*, Kevin Baird, Matt and Becki Phillips-Long for information on *Boiga dendrophila* and *Calliophis intestinalis*, and Olya Milenkaya and anonymous reviewers for improving this work.

The geographic distribution of amphibians and reptiles in Tennessee has been well documented by Scott and Redmond (2002), and is regularly updated via online atlas (Scott and Redmond 2008). However, the southeastern region of Tennessee has not received the necessary attention or sampling effort to adequately document the presence of many common species. The following records will assist in filling these data gaps. All turtles were collected during a survey of riverine turtle populations in Marion and Hamilton counties, Tennessee. Other specimens were collected during biological field surveys in the aforementioned counties. Identification and distribution of species followed Powell et al. (1998) and Conant and Collins (1998), respectively. All specimens represent new county records. GPS datum is WGS 84. All county records were supported by Scott and Redmond (2008). All specimens were deposited in the University of

Tennessee at Chattanooga Natural History Museum Reptile Collection (UTC-R). Nomenclature follows Crother (2008). All specimens were independently verified by Timothy Gaudin (UTC) and Rico Walder (formerly of the Tennessee Aquarium).

TESTUDINES – TURTLES

***APALONE SPINIFERA* (Spiny Softshell)**. Marion Co.: Tennessee River Gorge, near Pryor Island (35.0714944°N, 85.5278806°W). Specimen captured in a 3-ft diameter hoop net trap baited with sardines and soybean oil. 14 August 2004. Thomas P. Wilson, Christopher B. Manis, Stefan L. Moss, Robert M. Minton. UTC-R Digital Collection 4658.

***GRAPTEMYS GEOGRAPHICA* (Northern Map Turtle)**. Marion Co.: Tennessee River Gorge, in a 3 x 5-ft basking-style trap (35.0899833°N, 85.401125°W). 14 July 2000. Christopher B. Manis. UTC-R Digital Collection 4659.

***STERNOTHERUS MINOR PELTIFER* (Stripe-necked Musk Turtle)**. Marion Co.: Tennessee River Gorge, in a 3-ft diameter hoop net-style trap (35.0900889°N, 85.3967583°W). 12 July 2000. Christopher B. Manis. UTC-R 4660.

***STERNOTHERUS ODORATUS* (Eastern Stinkpot)**. Marion Co.: Tennessee River Gorge, in a 3-ft diameter hoop net-style trap (35.0883278°N, 85.391°W). 13 June 2000. Christopher B. Manis. UTC-R 4569.

SQUAMATA – LIZARDS

***OPHISAURUS ATTENUATUS* (Slender Glass Lizard)**. Hamilton Co.: Walden Ridge (35.1999639°N, 85.3282083°W). Adult specimen found dead in an open meadow. September 2008. Evan Collins. UTC-R 4662.

***PLESTIODON FASCIATUS* (Common Five-lined Skink)**. Hamilton Co.: 0.3 miles S of Morrison Springs and Mountain Creek Road intersection. Specimen found in garden of residence (35.1223583°N, 85.3130611°W). 06 June 2009. Thomas P. Wilson and Tabitha M. Wilson. UTC-R 4663. Marion Co.: 2.6 mi. W on US-41 from the Marion Co. line (35.0196444°N, 85.4585722°W). 22 July 1997. UTC-R 40. Timothy Gaudin.

SQUAMATA – SNAKES

***CROTALUS HORRIDUS* (Timber Rattlesnake)**. Marion Co.: Tennessee River Gorge, crossing the Tennessee River, near Pot Point (35.0891417°N, 85.3899667°W). First county record. 2 August 2007. Thomas P. Wilson, Christopher B. Manis, Stefan L. Moss, Robert M. Minton. UTC-R Digital Collection 4664.

***LAMPROPELTIS GETULA* (Common Kingsnake)**. Hamilton Co.: Stuart Heights neighborhood at 3100 Lockwood Drive at intersection (35.1025417°N, 85.2850389°W). First county record. 11 July 1999. UTC-R 45. Timothy Gaudin.

***REGINA SEPTEMVITTATA* (Queensnake)**. Marion Co.: Found dead on road (35.0899639°N, 85.3996833°W). First county record. 01 April 2008. UTC-R 4666. Jennifer Grubb, Jill Harrison-Whitaker, and Thomas P. Wilson.

***STORERIA DEKAYI* (Dekay's Brownsnake)**. Marion Co.: Terrestrial area associated with Mullins Cove (35.0687306°N, 35.0687306°W). 24 November 1971. UTC-R 14. John Shadwick.

***THAMNOPHIS SIRTALIS* (Common Gartersnake)**. Hamilton Co.: Found dead on Mountain Creek Road (35.148325°N, 85.297925°W). 24 April 2010. UTC-R 4665. Thomas P. Wilson and Tabitha M. Wilson. Marion Co.: Terrestrial area associated with Mullins Cove (35.0664389°N, 85.4762°W). 04 September 1971. UTC-R 35. Kent Tapper, Georgia Tapper, and Carrol Tapper.

Acknowledgments.—We thank Charles Nelson, George Benz, Dave Collins, John Scharer, Tim Walsh, Jennifer Soren, and Jill Harrison. For reviewing earlier versions of this manuscript, we are indebted to Mark Schorr, David Aborn, and Tim Gaudin. Logistical support was provided by the University of Tennessee at Chattanooga Department of Biological and Environmental Sciences, Tennessee River Gorge Trust, Tennessee Aquarium and Tennessee Aquarium Research Institute. Funding was provided by the Lupton Renaissance Gift Fund (UCF#R040152003). Specimens were collected and processed pursuant to permits from the TWRA (1534, 3082) and University approved animal use protocols (IACUC 1205TPW01, 0506TPW02).

Amphibian and Reptile Distribution Records for Louisiana – II

The following distributional records for Louisiana amphibians and reptiles have accumulated since an earlier list of records (Boundy 2004), and are based on Dundee and Rossman (1989) and subsequent sources. Many of the new records are the result of specimens collected for the Natural Science Museum at Louisiana State University (Baton Rouge, LSUMZ), whereas others were detected in a survey of the collection of the Louisiana State University at Shreveport Natural Science Museum (LSUS). Identifications of specimens at LSUS were verified by Laurence Hardy and/or Amanda Lewis. Specimens at LSUMZ were verified by Eric Rittmeier or Douglas Rossman. All specimens represent parish records unless otherwise noted. Geographic coordinates are based on NAD83 datum.

CAUDATA — SALAMANDERS

***AMBYSTOMA TALPOIDEUM* (Mole Salamander).** Webster Parish: 3.4 km E, 0.8 km of N Doyline (32.5392°N, 93.3691°W). 3 February 1994. Laurence M. Hardy. LSUS 8597–8600. A second specimen, LSUS 8601, was collected in this parish. Winn Parish: Kisatchie National Forest, Winn Ranger District, compartment 22 (approximately 32.10°N, 92.87°W). 30 April 2005. E. S. Walsh. LSUS 8977.

***AMPHIUMA TRIDACTYLUM* (Three-toed Amphiuma).** Claiborne Parish: Corney Lake (approximately 32.91°N, 92.74°W). 1 April 1989. K. Lutsch and D. Wyrick. LSUS 7587–7588.

***DESMOGNATHUS CONANTI* (Spotted Dusky Salamander).** DeSoto Parish: 18.4 km SE of Mansfield, Sec 7 at Cane Branch (31.9479°N, 93.6319°W). 28 February 1981. Joe Hollenberg. LSUS 7956.

ANURA — FROGS

***ANAXYRUS* (= *BUFO*) *TERRESTRIS* (Southern Toad).** East Feliciana Parish: Gilead Road, 10.9–12.2 km S of LA 10 (approximately 30.81°N, 90.86°W). 14 May 2004. Jeff Boundy. LSUMZ 87975. A second specimen, LSUMZ 87977, was collected in this parish.

***ELEUTHERODACTYLUS CYSTIGNATHOIDES* (Rio Grande Chirping Frog).** East Baton Rouge Parish: Hawthorne Drive at Buttercup Drive, Baton Rouge (30.3796°N, 91.0723°W). 16 July 2007. John D. McVay. LSUMZ 90427. Castle Kirk Drive, Baton Rouge (30.3752°N, 91.1217°W). 27 September 2007. Patti Faulkner. LSUMZ 90640. This exotic species has been established at the latter site for at least three years (P. Faulkner, pers. comm.).

***GASTROPHRYNE CAROLINENSIS* (Eastern Narrow-mouthed Toad).** West Carroll Parish: Big Colewa Wildlife Management Area, Bearskin Unit (32.42°N, 91.38°W). 28 April 2010. Jeff Boundy and Beau Gregory. LSUMZ 93800.

***HYLA CINEREA* (Green Treefrog).** La Salle Parish: N end of Dewey Wills Wildlife Management Area (31.5124°N, 92.0372°W). 9 May 2007. Jeff Boundy. LSUMZ 90290.

***LITHOBATES* (= *RANA*) *CATESBEIANUS* (American Bullfrog).** Red River Parish: Bayou Pierre, East side of Bayou Pierre Bridge (32.1921°N, 93.5545°W). 22 September 2004. Malcolm McCallum and E. S. Walsh. LSUS 8863.

***LITHOBATES* (= *RANA*) *CLAMITANS* (Green Frog).** West Carroll Parish: Big Colewa Wildlife Management Area, Bearskin Unit (32.42°N, 91.38°W). 28 April 2010. Jeff Boundy and Beau Gregory. LSUMZ 93798, 93799.

TESTUDINES — TURTLES

***DEIROCHELYS RETICULARIA* (Chicken Turtle).** DeSoto Parish: 0.4 km S, 5.6 km E of Longstreet (32.0932°N, 93.8904°W). 14 April 1972. Marilyn Brumley. LSUS 8146.

***MACROCHELYS TEMMINCKII* (Alligator Snapping Turtle).** DeSoto Parish: Toledo Bend, near Ace's Camp outside Logansport (approximately 31.91°N, 93.91°W). No date or collector. LSUS 8425. Livingston Parish: right descending bank of Natalbany River at LA 1048 (30.4820°N, 90.5568°W). 29 October 2004. Jeff Boundy. LSUMZ 88083.

***STERNOTHERUS CARINATUS* (Razor-backed Musk Turtle).** Bossier Parish: 0.4 km S, 0.8 km W of Magenta (32.3719°N, 93.5966°W). 7 February 1994. C. Cormier. LSUS 6224–6227. A more recent specimen, LSUS 8799, was collected in this parish. East Feliciana Parish: lake just E of LA 63, 0.8 km N of LA 37 (30.7360°N, 90.8547°W). 13 August 2005. Jeff Boundy. LSUMZ 88909–88912.

***TRACHEMYS SCRIPTA* (Pond Slider).** Winn Parish: LA 501, 2.4 km S of Brewton's Mill (32.0992°N, 92.8408°W). 10 June 1999. Laurence M. Hardy. LSUS 8427.

SQUAMATA — LIZARDS

***ANOLIS CAROLINENSIS* (Green Anole).** Cameron Parish: Peveto Beach, Johnsons Bayou (29.7490°N, 93.6583°W). 15 November 2003. Steven W. Cardiff and Donna L. Dittman. LSUMZ 87671–87674.

***ANOLIS SAGREI* (Brown Anole).** St. Tammany Parish: US 190 in town of Covington (approximately 30.46°N, 90.09°W). September 1998. Tom Lorenz. LSUMZ 80085.

***HEMIDACTYLUS TURCICUS* (Mediterranean Gecko).** Livingston Parish: Jordan Drive, Denham Springs (30.5027°N, 90.9326°W). 8 July 2007. Beau Gregory. LSUMZ 90415. Plaquemines Parish: Headquarters of Pass A Loutre Wildlife Management Area (29.1259°N, 89.2069°W). 23 October 2007. Beau Gregory. LSUMZ 90684.

New County Records for the Rolling Plains of North Texas

The rolling plains region of north-central Texas is part of the Kansan biotic province (Blair 1949; Werler and Dixon 2000). This region has been poorly sampled for reptiles and amphibians (Dixon 2000; Werler and Dixon 2000). Here, new records are reported from surveys of this region. County records were determined by examination of Dixon (2000) and issues of Herpetological Review published since Dixon (2000). All voucher specimens and photographs are deposited at the Texas Natural History Collections (TNHC), Texas Memorial Museum. Travis J. LaDuc verified all specimens. Lat/long data were obtained via a handheld GPS using the WGS84 datum. All collections were made under Scientific Collecting Permit SPR-0305-036, issued by Texas Parks and Wildlife.

ANURA — FROGS

***BUFO DEBILIS* (Green Toad)**. Motley Co.: Double Helix Ranch, ca. 6.4 air km NW of Dumont (33.85157°N, 100.55209°W). 22 June 2007. Collected by D. M. Hillis and G. B. Pauly. TNHC 67360. This specimen fills a gap in the distribution.

***GASTROPHRYNE OLIVACEA* (Western Narrow-mouthed Toad)**. Motley Co.: Double Helix Ranch, ca. 5.8 air km NW of Dumont (33.84026°N, 100.53489°W). 21 June 2007. Collected by D. M. Hillis and G. B. Pauly. TNHC 67402. Previously reported from Floyd and Cottle counties, which are to the west and east of Motley Co., respectively.

***PSEUDACRIS CLARKII* (Spotted Chorus Frog)**. King Co.: Roadside ditch along U.S. Rt. 83, 0.8 km N of FM 193 (34.78110°N, 100.33865°W). 30 May 2007. Collected by G. B. Pauly. TNHC 67421–67423). These males were observed calling in a chorus of numerous *Gastrophryne olivacea* and one *Anaxyrus debilis*. Previously reported from Stonewall and Knox counties, which are to the south and east of King Co., respectively.

SQUAMATA — LIZARDS

***PHRYNOSOMA CORNUTUM* (Texas Horned Lizard)**. Foard Co.: Co. Rd. 361, 9.6 km SW of FM 263 (33.84260°N, 99.90765°W). 22 June 2007. Observed by D. M. Hillis and G. B. Pauly. TNHC 84400 (photo voucher). This specimen fills a gap in the distribution.

SQUAMATA — SNAKES

***ARIZONA ELEGANS* (Glossy Snake)**. Cottle Co.: DOR, U.S. Rt. 83, 0.5 km N of FM 3256 (34.12302°N, 100.29845°W). 29 May 2007. Collected by G. B. Pauly. TNHC 67574. This specimen fills a gap in the distribution.

***COLUBER CONSTRICTOR* (North American Racer)**. Foard Co.: DOR, U.S. Hwy 70, 3.5 km E of Cottle/Foard Co. line (34.07560°N, 100.01220°W). 22 June 2007. Collected by D. M. Hillis and G. B. Pauly. TNHC 67575. This specimen fills a gap in the distribution.

***LAMPROPELTIS GETULA* (Common Kingsnake)**. Foard Co.: DOR, U.S. Hwy 70, 3.2 km W of Crowell (33.98934°N, 99.76497°W). 22 June 2007. Collected by D. M. Hillis and G. B. Pauly. TNHC 67578. This specimen fills a gap in the distribution.

***LAMPROPELTIS TRIANGULUM* (Milksnake)**. Motley Co.: Double Helix Ranch, ca. 5.8 air km NW Dumont (33.84026°N, 100.53489°W). 21 June 2007. Observed by D. M. Hillis and G. B. Pauly. TNHC 84401 (photo voucher). This species is largely unrecorded from the rolling plains region of north Texas.

***PANTHEROPHIS EMORYI* (Great Plains Ratsnake)**. Dickens Co.: FM 193, 4.2 km W of Dickens/King Co. line (33.78112°N, 100.56343°W). 29 May 2007. Collected by G. B. Pauly. TNHC 67563. This specimen fills a gap in the distribution.

***SONORA SEMIANNULATA* (Western Groundsnake)**. Motley Co.: Double Helix Ranch, ca. 6.4 air km NW Dumont (33.85157°N, 100.55209°W). 29 May 2007. Collected by G. B. Pauly. TNHC 67583. This specimen fills a gap in the distribution.

***THAMNOPHIS PROXIMUS* (Western Ribbonsnake)**. Stonewall Co.: DOR, U.S. Rt. 83, 13.1 km N of U.S. Rt. 380 (33.29410°N, 100.24737°W). 23 June 2007. Collected by D. M. Hillis and G. B. Pauly. TNHC 67587. Previously reported from Fisher, Jones, and Haskell counties, which are to the south and east of Stonewall Co.

Acknowledgments.—I am grateful to D. M. Hillis and J. J. Bull for access to the Double Helix Ranch, to D. M. Hillis for field assistance, and to T. J. LaDuc for verifying all specimens.

NATURAL HISTORY NOTES

The Natural History Notes section is analogous to Geographic Distribution. Preferred notes should 1) focus on observations in the field, with little human intrusion; 2) represent more than the isolated documentation of developmental aberrations; and 3) possess a natural history perspective. Individual notes should, with few exceptions, concern only one species, and authors are requested to choose a keyword or short phrase which best describes the nature of their note (e.g., Reproduction, Morphology, Habitat, etc.). Use of figures to illustrate any data is encouraged, but should replace words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles submitted to this section will be reviewed and edited prior to acceptance. Notes concerning captive animals should be directed to Herpetological Husbandry (see inside front cover for section editor contact information).

Electronic submission of manuscripts is requested (as Microsoft Word or Rich Text format [rtf] files, as e-mail attachments). Color figures can be submitted electronically as JPG files, although higher resolution TIFF or PDF files will be requested for publication. Please DO NOT send graphic files as imbedded figures within a text file. Additional information concerning preparation and submission of graphics files is available on the SSAR web site at: http://www.ssarherps.org/HRinfo.html. Manuscripts should be sent to the appropriate section editor: **Jackson Shedd** (crocodilians, lizards, and *Sphenodon*; jackson.shedd@gmail.com); **Charles Painter** (amphibians; charles.painter@state.nm.us); **J. D. Willson** (snakes; hr.snake.nhn@gmail.com); and **James Harding** (turtles; hardingj@msu.edu).

Standard format for this section is as follows: SCIENTIFIC NAME, COMMON NAME (for the United States and Canada as it appears in Crother [ed.] 2008. *Scientific and Standard English Names of Amphibians and Reptiles of North America North of Mexico*. SSAR Herpetol. Circ. 37:1–84, available from SSAR Publications Secretary, ssar@herplit.com; for Mexico as it appears in Liner and Casas-Andreu 2008, *Standard Spanish, English and Scientific Names of the Amphibians and Reptiles of Mexico*. Herpetol. Circ. 38:1–162), KEYWORD. DATA on the animal. Place of deposition or intended deposition of specimen(s), and catalog number(s), if relevant to your report. Then skip a line and close with SUBMITTED BY (give name and address in full—spell out state names—no abbreviations). (NCN) should be used for common name where none is recognized. References may be briefly cited in text (refer to this issue for citation format).

Recommended citation for notes appearing in this section is: Medina, P., and R. L. Joglar. 2008. *Eleutherodactylus richmondi*: reproduction. Herpetol. Rev. 39:460.

CAUDATA — SALAMANDERS

***GYRINOPHILUS PORPHYRITICUS* (Spring Salamander). ALBINISM.** *Gyrinophilus porphyriticus* is a rather large, stout-bodied plethodontid with a salmon to pinkish orange ground color overlain with black streaks or spots that ranges from southern Quebec and southern Maine to central Alabama. In more mountainous regions of western North Carolina, Spring Salamanders can be found in or near springs, seepages, small streams, and wet roadside ditches (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington, DC. 587 pp.). Herein we report on the observation of a wild albino specimen of *G. porphyriticus*.

At ca. 2140 h on 18 June 2011, we observed a sub-adult *G. porphyriticus* that appeared to lack black pigmentation. This *G. porphyriticus* was found on a wet rock wall above a ditch along the eastern edge of FR 70 (Tate City Road) in the Nantahala National Forest of Clay Co., North Carolina, USA, ca. 0.4 km N of the Georgia state line (34.99586°N, 83.55569°W, WGS 84; elev. 781 m). It still appeared to exhibit red and yellow pigmentation, giving it an overall light orange hue (Fig. 1A). The

FIG. 1. A) Albino *Gyrinophilus porphyriticus* observed in Clay Co., North Carolina, USA. B) Close-up of the head.

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

canthus rostralis on this specimen was evident, although the typical dark border was absent. The eyes were pale yellow with a red horizontal line through the center and the pupils were red instead of black (Fig. 1B). The specimen was photographed and left *in situ*.

Albinism has been reported for larval *G. porphyriticus* (Brandon and Rutherford 1967. Am. Midl. Nat. 78[2]:537–540), however, to our knowledge this is the first documentation of albinism in a post-metamorphic specimen.

We thank Danté B. Fenolio and Joseph R. Mendelson, III for editorial assistance.

ROBERT L. HILL, Department of Research and Conservation, Atlanta Botanical Garden, Atlanta, Georgia 30309, USA (e-mail: rhill@zooatlanta.org); **DANIEL PERELLA** and **RENATA IBELLI VAZ,** Setor de Répteis, Fundação Parque Zoológico de São Paulo, São Paulo, Brazil, 04301-905.

ANURA — FROGS

***ACRIS CREPITANS* (Northern Cricket Frog). FIRE ANT ENVENOMATION.** Red Imported Fire Ants (*Solenopsis invicta*) are an aggressive invasive species that have spread throughout much of the southeastern United States after being accidentally introduced into the port of Mobile, Alabama in the 1930s (Wojcik et al. 2001. Am. Entomol. 47:16–23). A growing number of studies have reported both direct and indirect negative effects of *S. invicta* on native amphibians and reptiles (Allen et al. 1997. J. Herpetol. 31:318–321; Diffie et al. 2010. J. Herpetol. 44:294–296; Todd et al. 2008. Biol. Invasions 10:539–546). However, it is not known how frequently or to what extent *S. invicta* actively prey upon native herpetofauna, highlighting the importance of reporting anecdotal observations. Here I describe a natural agonistic encounter between a fire ant and a Northern Cricket Frog.

At ca. 0915 h on 9 June 2011,100 m S of Rome Pond, 150 m N of U.S. Hwy. 29, Covington Co., Alabama, USA (31.142559°N, 86.673418°W; WGS 84), I observed a Red Imported Fire Ant stinging an adult *Acris crepitans*. The ant had pierced the skin of the frog's right forelimb with its mandibles and was seen inserting its stinger repeatedly. This attack was observed more than 5 m away from the closest fire ant mound, in an open grassy area. I removed the ant to examine the frog for species identification. Upon identification, the frog was released at its point of capture. To the best of my knowledge, this is the first account of a *S. invicta* envenomating *A. crepitans*.

NICOLE A. FREIDENFELDS, Pennsylvania State University, 208 Mueller Laboratory, University Park, Pennsylvania 16802, USA; e-mail: nicole.freidenfelds@gmail.com.

***ANAXYRUS AMERICANUS CHARLESMITHI* (Dwarf American Toad). NEMATODE PARASITE.** Several parasites have been reported from the Dwarf American Toad. Herein we report a new host record for a nematode parasite of *Anaxyrus* (=*Bufo*) *americanus charlesmithi*.

A single *A. a. charlesmithi* was collected on 29 May 1994 from 3.2 km SW Shannon Hills, Saline Co., Arkansas (34.608622°N, 92.433261°W) and examined for helminths. It was killed with a dilute chloretone solution and a midventral incision was made to expose the entire length of the digestive tract. Two nematodes were removed from the rectum and cleared on glass slides with undiluted glycerol. These were identified as a male and female *Cosmocercoides variabilis* (Harwood 1930) Travassos, 1931. Voucher specimens were deposited in the United States National Parasite Collection (USNPC), Beltsville, Maryland as USNPC 84402. A host voucher is deposited in the Arkansas State University Herpetological Collection (ASUMZ), State University, Arkansas as ASUMZ 19701.

Previous bufonid hosts of *C. variabilis* include *A. americanus americanus* (Vanderburgh and Anderson 1987. Can. J. Zool. 65:1666–1667), *A. boreas* (Goldberg et al. 1999. Bull. S. California Acad. Sci. 98:39–44), *A. debilis debilis* (McAllister et al. 1989. Proc. Helminthol. Soc. Washington 56:162–167), *A. hemiophrys* (Bursey and Goldberg 1998. J. Parasitol. 84:617–618.), *A. quercicus* (Goldberg and Bursey 1996. Alytes 14:122–126); *A. terrestris* (Harwood 1932. Proc. U.S. Nat. Mus. 81:1–71), and *A. woodhousii woodhousii* (McAllister et al., *op. cit.*).

This nematode has an extensive range and has been reported previously from Arizona, Arkansas, California, Florida, Idaho, Illinois, Iowa, Louisiana, Massachusetts, Michigan, Nebraska, New York, North Carolina, North Dakota, Ohio, Oklahoma, Oregon, South Dakota, Texas, Utah, Virginia, Washington, West Virginia, Wisconsin, Alberta, British Columbia, New Brunswick and Quebec, Canada , Baja California Norte, Mexico, Costa Rica, and Panama (Bursey et al. 2007. Comp. Parasitol. 74:108–140).

***BUFO* (= *ANAXYRUS*) *HOUSTONENSIS* (Houston Toad). HEAD-START JUVENILE DISPERSAL.** The Houston Toad is a federally endangered amphibian endemic to east-central Texas. A head-starting program was initiated in 2007 as a population recovery strategy for *Bufo houstonensis*. As part of the program, wild laid eggs are collected, reared at the Houston Zoo and post-metamorphosed juveniles are released to their natal pond. A genetic mark-recapture technique was developed to monitor the success of the head-starting program. Microsatellite markers were used to reconstruct family relationships based on the probability of individuals sharing alleles identical by descent. A small sample of tadpoles per egg strand (between 8 and 80) was sacrificed to obtain a genotypic "fingerprint" for 29 head-started egg strands. This mark-recapture technique accurately assigned 94–97% of all family members to their appropriate egg cohort (Vandewege 2011. Unpubl. MS. thesis, Texas State Univ. San Marcos, Texas. 84 pp.). A tissue sample was collected from any adult or juvenile captured after the release of head-starts to assess the frequency of captive-reared *B. houstonensis* on the landscape.

During a *B. houstonensis* reproduction survey conducted on 18 April 2010, an egg strand was harvested from a temporary pond on the Griffith League Ranch, Bastrop County, Texas, USA. Post-metamorphosed juveniles from this egg strand (N = 1908) with a mean weight of 0.09 g were released at their natal pond on 21 May 2010. On 23 June 2010 a juvenile *B. houstonensis* weighing 3.8 g was collected from a pitfall trap 1.34 km from the release point. This juvenile had a DNA genotype 100% consistent with the head-started individuals released five weeks prior. This is the longest confirmed distance a juvenile *B. houstonensis* has moved. Prior to this record, *B. houstonensis* had been monitored up to 50 m (Greuter 2004. Unpubl. MS. thesis, Texas State Univ. San Marcos, Texas 80 pp.) and 100 m (Hillis et al. 1984. J. Herpetol. 18:56–72) from their natal pond. A previous technique using fluorescent pigment proved successful for tracking daily movement patterns (Swannack et al. 2006. Herpetol. Rev. 37[2]:199–200), whereas this new technique allowed juvenile

B. houstonensis to be monitored over long distances and time periods. This record illustrates that juvenile *B. houstonensis* are capable of moving long distances in a short period of time. Although it remains unclear how far *B. houstonensis* typically disperse between metamorphosis and adulthood, this observation highlights the importance of increasing habitat connectivity in a highly fragmented environment for the conservation and recovery of this endangered species.

BROWN** and **MICHAEL R. J. FORSTNER** (e-mail: mf@txstate.edu), Department of Biology, Texas State University, San Marcos, Texas 78666, USA.

***GASTROPHRYNE CAROLINENSIS* (Eastern Narrow-mouthed Toad). PREDATION.** A series of strong scattered thunderstorms passed through the Central Savannah River Area (CSRA) in Georgia and South Carolina, USA on 28 June 2011 from ca. 1400–2100 h and filled a few patchily-distributed depression wetlands with a few centimeters of standing water. One small (ca. 20 m × 10 m) wetland (Risher Pond Sloughs, Barnwell Co., South Carolina) hosted an anuran breeding assemblage of ca. 30 *Hyla femoralis*, 20 *H. squirella*, 20 *Gastrophryne carolinensis*, 6 *Pseudacris ocularis*, and 10 *H. chrysoscelis* by 2138 h. At 0016 h, an adult (499 mm SVL; 32.6 g) female *Thamnophis s. sauritus* was found ca. 1.7 m above the surface of the water in a stand of dead *Panicum hemitomon*. The *T. s. sauritus* was in the process of swallowing a gravid female *G. carolinensis* (32 mm SVL; 2.25 g) and moved slowly around in the *Panicum* with the front of the toad hanging out of the right side of its mouth. After observing the snake for four minutes, we captured it and removed the *G. carolinensis* from its mouth. Both animals were returned to the lab for measurements. The *G. carolinensis* was dead by 0800 h the next morning and the *T. s. sauritus* was released unharmed post-processing without any noticeable ill effects from exposure to the *G. carolinensis*. *Gastrophryne carolinensis* are toxic to many predators, which will often refuse to eat them (Garton and Mushinsky 1979. Can. J. Zool. 57:1965–1973), and few firsthand accounts of *G. carolinensis* predation exist, possibly because of this toxicity. *Thamnophis s. sauritus* is a generalist amphibian predator that is known to consume a wide variety of prey (Brown 1979. Brimleyana 1:113–124; Carpenter 1952. Ecol. Monogr. 4:235–258). Only one account of a *T. sauritus* eating a *G. carolinensis* exists as a personal communication from R. W. Gaul Jr. in North Carolina (Palmer and Braswell 1995. Reptiles of North Carolina. Univ. North Carolina Press, Chapel Hill, North Carolina), but to our knowledge, this is the first confirmed firsthand observation of a *T. s. sauritus* depredating a *G. carolinensis*.

Animals were captured under scientific research permit G-11-03 from the South Carolina Department of Natural Resources. Funding for this research was provided by the National Science Foundation (Awards DEB-0242874 and DBI-0139572) and the Savannah River Ecology Laboratory under Financial Assistance Award DE-FC09-96SR18-546 between the University of Georgia and the U.S. Department of Energy.

***HYALINOBATRACHIUM ORIENTALE* (Oriental Glass Frog). MALE PARENTAL CARE.** One clade of glass frogs, the Hyalinobatrachinae, is distributed in tropical Central America, the tropical Andes, the coastal ranges of Venezuela, the island of Tobago, the upper Amazon Basin, and the Guiana Shield. Males of all species of *Hyalinobatrachium* call from the underside of leaves and females deposit their eggs on the underside of leaves; at least seven species have been reported to have males guard the eggs, a behavior that is considered a primary homology of the genus (Guayasamin et al. 2009. Zootaxa 2100:1–97; Kubicki 2007. Ranas de Vidrio de Costa Rica /Glass Frogs of Costa Rica. Editorial INBio, Santo Domingo de Heredia). Here we report the first observations of male *Hyalinobatrachium orientale* attending eggs. On the evenings of 4 and 5 June 2011 we detected the calls of male *H. orientale* along several of the streams that drain Tobago's Main Ridge, and on the evening of 5 June we observed and photographed males next to egg masses (Fig. 1), males covering egg masses with their bodies (Fig. 2), and guardian males calling. Calling males were 1–10 m above the stream and minimally separated by 2–3 m; usually the separation distance was greater.

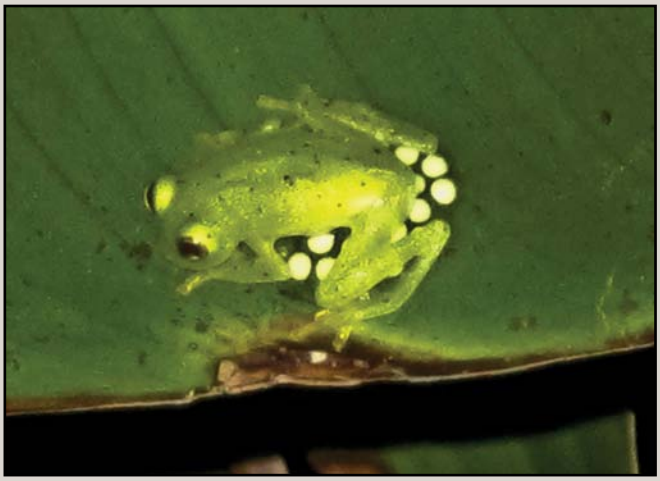

FIG 1. A male *Hyalinobatrachium orientale* covering an egg mass with its body, behavior that may reduce desiccation or deter predators. The leaf was about 4 m above the stream.

FIG 2. A male *Hyalinobatrachium orientale* calling from the underside of a leaf.

The male frogs were often on the undersides of *Heliconia* leaves, a position that may offer protection from desiccation, falling rain drops, and predators. Also, the leaves supporting the frogs and egg masses were frequently covered by a second leaf that would likely provide additional protection from wind and sun. Crabs were observed on the same plants that contained frogs and they may be a primary factor in the frogs of this genus selecting the undersides of leaves for calling stations and egg laying.

JOHN C. MURPHY, Division of Amphibians and Reptiles, Field Museum of Natural History, Chicago, Illinois 60605, USA (e-mail: fordonia1@comcast.net); **STEVLAND CHARLES**, Department of Biology, Howard University, Washington, DC 20059, USA; **JOSHUA TRAUB**, Division of Amphibians and Reptiles, Field Museum of Natural History, Chicago, Illinois 60605, USA.

***HYLA ARBOREA* (European Tree Frog). POTENTIAL CANNIBALISM.** Cannibalism is widespread in a variety of animals, including amphibians (Elgar and Crespi 1992. Cannibalism: Ecology and Evolution Among Diverse Taxa. Oxford University Press, Oxford, New York. 376 pp.). Cannibalism may occur during food shortages, desiccation of the habitat, or because of a high concentration of individuals (Crump 1983. Am. Nat. 121[2]:281–289; Pfennig and Frankino 1997. Evolution 51:1993–1999; Summers 1999. Oecologia 119:557–564; Michimae and Wakahara 2001. Behav. Ecol. Sociobiol. 50:339–345.). Studies show that cannibalistic individuals have a higher growth rate, a larger size at metamorphosis, a greater likelihood of survival, and better reproductive parameters (Fox 1975. Annu. Rev. Ecol. Evol. Syst. 6:87–106; Polis 1981. Annu. Rev. Ecol. Evol. Syst. 12:225–251; Crump 1990. Copeia 1990[2]:560–564; Babbit and Meshaka 2000. Copeia 2000[2]:469–474). Cannibalism in tadpoles of *Hyla intermedia* as a result of drying habitat was described by Grant and Halliday (2011. Herpetol. Rev. 42[1]:86).

FIG. 1. *Hyla arborea* tadpoles with damaged caudal fins.

On 20 July 2007 on the Krk island in Croatia (45.03°N, 14.55°E, 54 m elev.), we observed different stages of *Hyla arborea* tadpoles that exhibited noticeable signs of damage to the caudal fin, especially the smaller individuals (Fig. 1). No dead specimens were observed, and potential natural predators (e.g., *Dytiscus* sp., *Pelophylax ridibundus*, *Natrix natrix*) were not found associated with the tadpoles. The habitat was completely unnatural, a small enamel livestock tank with drying aquatic habitat and dense larval aggregations. The tank was about 100 × 40 × 50 cm, with water ca. 30 cm deep. We estimated ca. 150–200 tadpoles ranging in size from 1–2.5 cm. Although direct cannibalism was not observed, the size differentiation and high density of individuals may of lead to the wounds observed.

***HYLA AVIVOCA* (Bird-Voiced Treefrog). CONSTRUCTED WETLAND COLONIZATION.** At the northern end of its range, *Hyla avivoca* populations have been extirpated or reduced in size due to drainage of Bald Cypress (*Taxodium distichum*) and Tupelo Gum (*Nyssa aquatica*) swamps (Redmer et al. 1999a. Illinois Nat. Hist. Surv. Bull. 36:37–66). Many remaining *H. avivoca* populations are isolated from each other by extensive deforested areas such as agricultural fields.

In the Cache River drainage of southern Illinois, USA, government agencies and private conservation groups are acquiring and reforesting cropland, and constructing wetlands. The Nature Conservancy's Grassy Slough Preserve (GSP) is an 1123-ha former vegetable farm bisected by a channelized portion of the Cache River in Johnson Co., Illinois. Fifteen shallow (< 2 m) wetlands (0.9–47.9 ha in area) were constructed or restored on GSP in 1999 and 2000, and seedling oaks (*Quercus* spp.) and hickories (*Carya* spp.) were planted on intervening uplands from 1999–2002. I studied herpetofaunal colonization of constructed wetlands from 2001–2004, when upland vegetation was dominated by pioneering herbaceous vegetation that over-topped the planted trees, and wetlands were vegetated principally by algae, Cocklebur (*Xanthium commune*), and Water Primrose (*Jussiaea repens*). Although I heard *H. avivoca* vocalizing from forested wetlands north and south of the former agricultural fields in 2000, *H. avivoca* was not among the 35 herpetofaunal species encountered at newly-constructed wetlands (Palis 2007. Trans. Illinois State Acad. Sci. 100:177–189).

On 15 June 2011, I heard choruses of *H. avivoca* in one restored and two constructed wetlands on GSP. Wetlands 3 and 1 are 65 m east and 485 m south, of a forest-bordered former channel of the Cache River where I heard *H. avivoca* calling in 2000 and 2008 (see Figure 1 in Palis 2007, *op. cit.*; available at www.il-acad-sci-org/publications). Wetland 3 (37.331222°N, 88.919189°W; geocoordinates derived from Google Earth), the restored wetland, is bordered on the west by a dense stand of young (≤ 7.5-m tall) trees including Sweetgum (*Liquidambar styraciflua*), Box Elder (*Acer negundo*), Red Maple (*Acer rubrum*), American Sycamore (*Platanus occidentalis*), Green Ash (*Fraxinus pennsylvanica*), oak, and River Birch (*Betula nigra*), as well as Buttonbush (*Cephalanthus*

occidentalis). The dense stand of young trees forms a continuous canopy from the wetland to the mature oak-hickory forest bordering the old river channel. With the exception of the forested edge, the wetland is treeless and vegetated principally with American Lotus (*Nelumbo lutea*), sedges (*Carex* spp.), rush (*Juncus* sp.), arrowhead (*Sagittaria* sp.), and widely-scattered buttonbush and Rose Mallow (*Hibiscus lasiocarpus*). An estimated 100± *H. avivoca* called from shrubs and trees along an ca. 500 m length of the western wetland edge examined from 2025–2150 h; air temp = 19°C). I also observed one amplectant pair. Wetland 1 (37.3269°N, 88.919061°W) is also dominated by herbaceous vegetation; ca. 90% of the surface is covered with Water Primrose. A continuous canopy of young trees occurs between Wetland 1 and Wetland 3 to the north. Approximately 10–15 *H. avivoca* called from a stand of Black Willow (*Salix nigra*) on the northern edge of the wetland (2155–2205 h). Wetland 10 (37.306528°N, 88.957806°W) is about 445 m north of a swamp where I heard *H. avivoca* in 2000. Dominant herbaceous and woody vegetation in Wetland 10 includes Water Primrose and Sweetgum, and a continuous canopy of young trees lies between Wetland 10 and the swamp. I heard approximately 10 *H. avivoca* vocalizing from the western end of Wetland 10 from 2247–2250 h.

Unlike 2001–2004, the uplands between constructed/restored wetlands and remnant forested wetlands support young forest in 2011. The tree canopy may provide an avenue for *H. avivoca* dispersal. Diet studies (Jamieson et al. 1993. Texas J. Sci. 45:45–49; Redmer et al. 1999b. Trans. Illinois State Acad. Sci. 92:271–275) suggest that *H. avivoca* is more arboreal than sympatric congeners (*H. chrysoscelis* and *H. cinerea*); therefore a continuous canopy may facilitate dispersal. Long-distance movements by *H. avivoca* away from breeding sites have also been observed in forested corridors (Palis 2010. Herpetol. Rev. 41:63–64).

At the northern end of its range, *H. avivoca* is thought to breed only in remnant Bald Cypress and/or Tupelo Gum swamps (Barbour 1971. Amphibians and Reptiles of Kentucky. Univ. Press of Kentucky, Lexington; Redmer et al. 1999a, *op. cit.*). My observations, however, indicate that newly-constructed/restored (11–12 years), herbaceous-dominated wetlands flanked by a rank growth of pioneering tree species can also serve as breeding habitat for *H. avivoca*. Thus, in Illinois, reforested agricultural fields and constructed/restored wetlands may provide habitat and movement corridors for *H. avivoca* which may, in turn, serve to expand and connect disparate populations of this state threatened species.

These observations would not have been possible without the kindness of E. Palmer; her assistance and companionship in the field is greatly appreciated.

JOHN G. PALIS, P.O. Box 387, Jonesboro, Illinois, USA; e-mail: jpalis@yahoo.com.

***HYLA CHRYSOSCELIS* (Cope's Gray Treefrog). CALLING/MATE CHOICE.** On 10 May 2011, at the Anita C. Leight Estuary Center (Abingdon, Maryland, USA; 39.45119°N, 76.26831°W), several *Hyla chrysoscelis* were observed using an unusual call to attract a female. Eight frogs were calling from four tanks of submerged aquatic vegetation. In two of the tanks, two males were positioned together on the inside of a corner with each frog on an adjoining wall (Fig. 1). The other four males were scattered around the tanks.

The frogs used the normal trilling call of *H. chrysoscelis*, but occasionally would use a chirping call that consisted of 3–5 rapid chirps rather than trills (Fig. 2). Chirping often was immediately

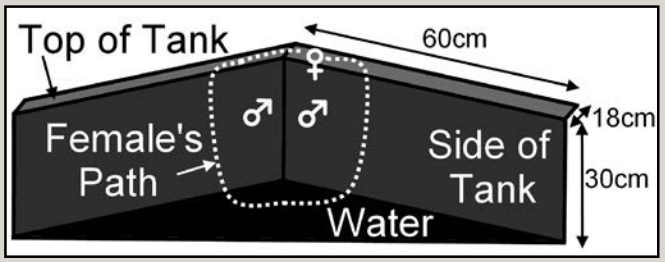

FIG. 1. An inside view of the corner of the tank from where the males called. Each male was on a separate wall and the female circled around them.

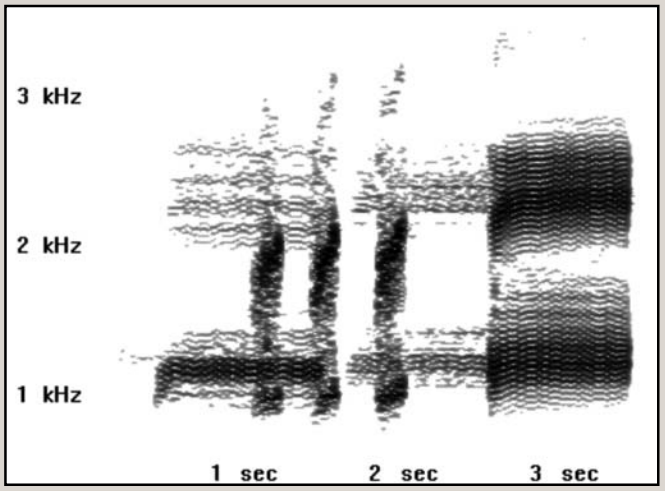

FIG. 2. A spectogram of a male *Hyla chrysoscelis* calling. Each of the three pulses between 1.25–2.25 seconds is a chirp, and the call from 2.5 seconds to the end is a normal trill. Everything else is background noise.

followed by trilling. Only the four males in the corners used the chirping call, but when one of them used it, the male that shared its corner almost always began chirping, and the two males in the corner of the other tank usually began chirping. The males also tended to discontinue chirping as soon as the other males stopped.

The frogs were easily disturbed while chirping. While trilling, they did not seem disturbed by observers, and would continue trilling even if a light was shone on them. While chirping, however, they almost always either stopped calling or switched to trilling the instant a light was shone on them.

As the frogs called, a female approached the corner where two of the males were calling. She began making loops around the males starting at the top, going down one side, through the water, up the other side, and back across the top (Fig. 1). She repeated this loop several times, sometimes switching directions part way through. The males seemed to use the chirping call in relation to her proximity. While going up or down the sides of the tank, the male that she was passing nearly always began rapidly and repeatedly chirping (usually stimulating the other male to chirp), and the chirping stopped once she reached the water or the top of the tank. Then, as she ascended or descended the other side, the other male would begin chirping (usually stimulating the original male to chirp). After making several loops, the female stopped at the top of the tank, and one of the males approached her. He walked up behind her, rubbed the side of her stomach with his front foot, and then mounted her. They both hopped into the water, and the female began laying eggs. It was

unclear how or if the female signaled her acceptance of that male over the other, but only one male moved, and the female showed no resistance when he approached.

It is interesting that the males used this short chirping call when the female was near because multiple studies have shown that female Gray Treefrogs (*Hyla versicolor*) prefer long calls to short ones (Fellers 1979. Copeia 1979:286–290; Schwartz et al. 2001. Behav. Ecol. Sociobiol. 49:443–455; Schwartz et al. 2004. Anim. Behav. 68:533–540). Perhaps, the handicap principal is at play. Chirping may be more noticeable to predators, thus putting the caller at a higher risk of predation, while simultaneously being highly attractive to females because it acts as a mechanism for judging male fitness. This makes sense in light of the observation that males were easily disturbed while chirping, and only the males that were in close proximity to another male chirped (the other males did not have as much direct competition and therefore did not need the more attractive but more dangerous call).

DONALD T. McKNIGHT, 1161 Priestford Road, Street, Maryland 21154, USA; e-mail: ytthirteenhundred@yahoo.com.

***HYPSIBOAS CREPITANS* (Rattle-voiced Treefrog). PREDATION.** Snakes are major predators of anurans and depending on preference, abundance, and habitat, they can exert the greatest predation pressure on a frog community. It is not uncommon in Neotropical regions to find Dipsadidae snakes preying on adult anurans in the breeding season near ponds (Wells 2007. The Ecology and Behavior of Amphibians. Univ. Chicago Press, Chicago, Illinois. 1148 pp.). *Leptodeira annulata* is a nocturnal arboreal snake that inhabits primary and secondary forests (Vitt 1996. Herpetol. Nat. Hist. 4:69–76). On 09 March 2010 at 2145 h we observed an individual *L. annulata* (TL = 760 mm, JZ 1521) preying on an adult male *Hypsiboas crepitans*, that by the time of our observation was almost completely ingested (Fig. 1). The tree frog was in calling activity on the grass at the edge of a semi temporary water body. The predation event occurred in a transition area between patches of Caatinga and Atlantic Rain Forest at Serra do Brejo Novo (13.94472°S, 40.10942°W; 700 m elev.), municipality of Jequié, state of Bahia, Brazil. *Hypsiboas crepitans* has a long breeding season associated with temporary or permanent ponds (Arzabe 1999. Rev. Brasil. Zool. 16[3]:851–864). As typical prolonged breeders, males spend consecutive nights calling at the same site, which increases their exposure to predators (Wells 2007, *op. cit.*). Predation accounts like the current one, although anectodal, help form a theoretical basis for larger studies about the importance of these events on the structure of anuran communities (Toledo 2005. Herpetol. Rev. 36[4]:395–400).

FIG. 1. Predation of an adult *Hypsiboas crepitans* by an individual of *Leptodeira annulata* (TL = 760 mm).

Voucher specimens are deposited in Juliana Zina's personal collection pending installation of the Natural History Museum of Jequié, at the Universidade Estadual do Sudoeste da Bahia, UESB, Jequié, Bahia, Brazil.

AMANDA S. F. LANTYER SILVA, Universidade Estadual Santa Cruz, Departamento de Ciências Biológicas, Rodovia Ilhéus/Itabuna, Km 16, 45662-900, Ilhéus, Bahia, Brazil (e-mail: asbiologa@gmail.com); **SÉRGIO SIQUEIRA** and **JULIANA ZINA**, Universidade Estadual do Sudoeste da Bahia, Departamento de Ciências Biológicas, Rua José Moreira Sobrinho, Jequiezinho, 45206-190, Jequié, Bahia, Brazil.

***KASSINA SENEGALENSIS* (Senegal Kassina). UNILATERAL HINDLIMB MICROMELY.** The discovery of frog populations with a large number of malformed individuals generated the need to list and better identify the causes of these malformations, a particularly relevant subject for the conservation of this highly endangered group (Lannoo 2008. Malformed Frogs. Univ. California Press, Berkeley, California. xvi + 270 pp.). Most of the documentation concerns metamorphosed individuals as the malformations are more conspicuous than in tadpoles. Furthermore, malformations in tadpoles can appear late in development, as in the cases involving limbs. A case of hindlimb developmental asymmetry was observed in a tadpole of *Kassina senegalensis* collected in an isolated lagoon with connections, Banhine National Park, Gaza Province, Mozambique (22.52917°S, 32.64583°E; WGS 84), 5 June 2005 and housed at the South African Institute for Aquatic Biodiversity, Grahamstown, South Africa under the collection number SAIAB 88010. The left hindlimb was in stage 40 (Fig. 1A) whereas the right hindlimb was in stage 32/33 (Fig. 1B) (Gosner 1960. Herpetologica 16:183–190). The right hindlimb presents a larger base than usually observed in other tadpoles as well as a strong indentation between the foot paddle and the proximal segment of the limb. However, the base of this hindlimb was still much less wide than in the stage 40 hindlimb. The cause of this developmental asymmetry is unknown. Frequency of this anomaly within the population is unknown as only this tadpole was collected at this locality. The malformations in amphibians are known to arise from pollution (radioactive pollution; agricultural or industrial chemicals), disease (infection by the fungus *Batrachochytrium dendrobatidis*) or parasitism, or may be of genetic origin (see Lannoo 2008, *op. cit.* for review). If the less developed hindlimb would stay shorter at the adult stage, this would be a case of unilateral hindlimb micromely. Another hypothesis could be a regenerating limb after failed predation. However, this limb and the surrounding tissue did not show the presence of any scars.

STÉPHANE GROSJEAN, Muséum national d'Histoire naturelle, Département Systématique and Evolution, UMR 7205 OSEB – Reptiles and Amphibiens, case 30, 25 rue Cuvier, 75005 Paris, France; e-mail: sgrosjea@mnhn.fr.

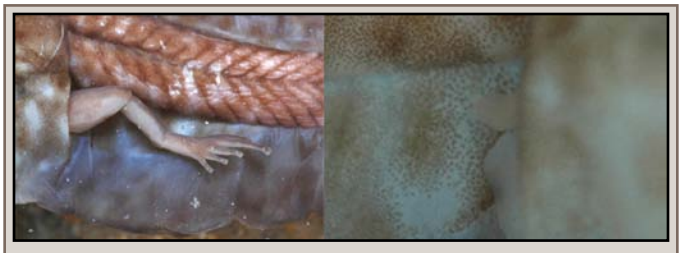

FIG 1. The left hindlimb in Gosner Stage 40 (left) and the right hindlimb in Gosner Stage 32/33 (right). Note that the two pictures are not at the same scale.

***LEPTOBRACHIUM ABBOTTI* (Lowland Litter Frog). MAXIMUM ELEVATION.** *Leptobrachium abbotti* is a stocky and large anuran (to 95 mm SVL) with a broad head and truncate but non-protruding snout, bulging dark eyes characterized by small bluish arcs, visible tympanums and supratympanic folds, rather smooth blackish top of the head and body, slightly granular venter distinctively mottled in black and white, slender and short limbs, rounded tips of digits, as well as toes webbed at bases (Inger 2005. The Systematics and Zoogeography of the Amphibia of Borneo. Natural History Publications [Borneo] Sdn. Bhd. Kota Kinabalu. 402 pp.; Malkmus et al. 2002. Amphibians and Reptiles of Mount Kinabalu [North Borneo]. A.R.G. Gantner Verlag K.G. Ruggell. 424 pp.). *Leptobrachium abbotti* occurs in Indonesia (West Sumatra, and Riau), and throughout Borneo (Sabah and Sarawak of Malaysia, Brunei Darussalam, and Kalimantan of Indonesia) (Das 2007. A Pocket Guide: Amphibians and Reptiles of Brunei. Natural History Publications [Borneo] Sdn. Bhd. Kota Kinabalu. viii + 200 pp.; Inger et al. 2004. *Leptobrachium abbotti*. *In* IUCN 2010. IUCN Red List of Threatened Species. Version 2010.4. <www.iucnredlist.org>. Accessed on 20 April 2011). The species inhabits the leaf litter of primary and old secondary forests with small to medium slow-moving streams with rocky bottoms for breeding, up to the maximum elevation of 1000 m (AmphibiaWeb: Information on amphibian biology and conservation. [web application] 2011. Berkeley, California: AmphibiaWeb. http://amphibiaweb.org/. Accessed on 20 April 2011; Haas and Das 2010. Frogs of Borneo. Frogs and Tadpoles of East Malaysia. Website: http://frogofborneo.org/. Accessed on 20 April 2011; Inger and Stuebing 2005. A Field Guide to the Frogs of Borneo. 2nd ed. Natural History Publications [Borneo] Sdn. Bhd. Kota Kinabalu. viii + 201 pp.). Herein we report a new altitudinal limit for *L. abbotti*.

On 8 Dec 2010 at 2050 h, an adult *L. abbotti* (51 mm SVL, 8.6 g) was found on a trail adjacent to Sungai Mayampak (5.9818°N, 116.5329°E; 1138 m elev.), Bundu Tuhan, Ranau District, West Coast Division, Sabah, Bornean Malaysia. Air temperature was 19.2°C, and relative humidity was 91%. The individual was found on the ground with minimal leaf litter as the trail is commonly used by local people. Due to the proximity to human settlement and forest, both groups of human commensal species (*Fejervarya limnocharis*) and forest-related species, such as *Ansonia longidigita*, *Leptolalax pictus*, *Megophrys nasuta*, and *Chaperina fusca*, occur along the trail. The finding suggests an extension of habitat for *L. abbotti*. As another *L. abbotti* has been found above 1000 m elev. (at 1081 m elev.) at Sungai Lidan (5.9844°N 116.5258°E), Bundu Tuhan, the new altitudinal limit finding holds taxonomic significance for *L. abbotti* to help avoid misidentification of the species at higher elevations. The specimens (Sungai Mayampak: HEP01824, and Sungai Lidan: HEP00536) were deposited in BORNEENSIS, the Bornean reference collection of the Institute for Tropical Biology and Conservation, Universiti Malaysia Sabah.

We are grateful to A. J. Lintanga for field assistance, J. Bulangai for field transportation, and the Haleluyah Retreat Centre for lodging. Collecting was conducted under permission of the Jawatankuasa Pemegang Amanah Hutan Simpanan dan Tanah Perumahan Bumiputera Kg. Bundu Tuhan, Ranau, to KBH. We also thank the Institute for Tropical Biology and Conservation, Universiti Malaysia Sabah for support.

***LEPTODACTYLUS* AFF. *HYLAEDACTYLUS*. DEFENSIVE BEHAVIOR.** It is well known that frogs are included in the diet of many predators, although they have evolved several defense mechanisms to survive (Duellman and Trueb 1994. Biology of Amphibians. MacGraw-Hill Book Co., New York. 670 pp.). Different species of amphibians, when touched and in danger, inflate their bodies with arms outstretched and legs close to the body and remain motionless (Wells 2007. The Ecology and Behavior of Amphibians. Univ. Chicago Press, Chicago, Illinois. 1400 pp.). This defensive behavior is known as thanatosis. Observations reported herein occurred during January to March 2011 in the municipality of São Gonçalo do Amarante, west coast of Ceará State, Brazil (3.51525°S, 38.9188°W). We captured about 20 individual *Leptodactylus* aff. *hylaedactylus* that, when handled in the field for measurements and photographs, exhibited thanatosis. They inflated their bodies and turned arms and legs upward with the arms outstretched and the legs close to the body, maintaining a belly-up position in the hand of an observer (Fig. 1). The animals remained motionless for about 2 minutes and then slowly returned to normal position. Soon after righting themselves, they attempted escape by leaping away. This behavior was photographed and filmed with a Sony HX1 digital camera. This behavior has been reported for other *Leptodactylus* and other anurans (Azevedo-Ramos 1995. Rev. Bras. Biol. 55[1]:45–47; Hartmann et al. 2003. Herpetol. Rev. 34:50; Zamprogno et al. 1998. Herpetol. Rev. 29:96–97) but this is the first report of this behavior in *Leptodactylus* aff. *hylaedactylus*.

FIG. 1. Adult *Leptodactylus* aff. *hylaedactylus* exhibiting death-feigning behavior following handling.

MARIA JULIANA BORGES-LEITE (e-mail: jborgesleite@gmail.com), **DIVA MARIA BORGES-NOJOSA** (e-mail: dmbnojosa@yahoo.com.br), and **DEMONTIER OSÓRIO DE MORAIS** (e-mail: demontiermorais@gmail.com), Núcleo Regional de Ofiologia, Universidade Federal do Ceará – NUROF/UFC, Campus do Pici, Bl. 905, Fortaleza, Ceará, Brazil, 60455-760.

***LEPTODACTYLUS MELANONOTUS* (Sabinal Frog). PREY.** *Leptodactylus melanonotus* is known to prey mainly on Coleoptera and Lepidoptera (Greding and Hellebuyck 1980. Carib. J. Sci. 16[1–4]:23–31), but it has also been reported to scavenge on ranid tadpoles (Lewis et al. 2008. Herpetol. Rev. 39[1]:79).

On 6 Oct 2009, an adult *Leptodactylus melanonotus* (sex unknown) was found biting the back leg of an adult *Tlalocohyla*

PHOTO BY OSCAR AVILA-LÓPES

FIG. 1. Predation on *Tlalocohyla smithi* by an adult *Leptodactylus melanonotus*, Colima, México.

smithi, in a drying pond about 0.8 km NE of Paticajo, municipality of Minatitlán, Colima, México (19.3061°N, 104.148°W, WGS 84; 483 m elev.). The *L. melanonotus* slowly started ingesting the *T. smithi*, hind legs first, and about 25 minutes later the entire *T. smithi* was ingested. The frogs were not captured, but several photographs were taken during the process and are deposited in the Digital Collection of the University of Texas at Arlington (UTADC 6255, 6656).

To our knowledge, this is the first report of a *Leptodactylus melanonotus* feeding on an adult anuran.

***LITORIA SERRATA* (Green-eyed Treefrog) and *LITORIA INFRAFRENATA* (White-lipped Treefrog). REPRODUCTIVE BEHAVIOR.** *Litoria serrata* and *L. infrafrenata* are tropical, arboreal frog species that inhabit rainforest and adjacent habitats of the Wet Tropics region of northeast Queensland, Australia. *Litoria serrata* is a relatively small species (SVL 37–80 mm) that is closely associated with streams and creeks where it breeds. *Litoria infrafrenata* is a considerably larger species (SVL 65–140 mm) that breeds in permanent or temporary ponds (Hoskin and Hero 2008. Rainforest Frogs of the Wet Tropics North-east Australia. Griffith Univ., Gold Coast, Australia. 96 pp.; Hero and Fickling 1994. A Guide to the Stream-dwelling Frogs of the Wet Tropics Rainforests. Dept. Zoology, James Cook University. Townsville, Qld. 27 pp.) Although examples of interspecific amplexus among frogs are relatively common (Grogan and Grogan 2011. Herpetol. Rev. 42: 89–90; Manzano and Corzas 2011. Herpetol. Rev. 42:84), Streicher et al. (2010. Herpetol. Rev. 41:208) commented on the lack of examples pertaining to tropical hylids. Herein I report one such example of amplexus between *L. serrata* and *L. infrafrenata*, despite differences in size and preferred breeding habitat.

At 1055 h on 11 Oct 1998, I observed a male *L. serrata* in amplexus with a small adult (sex unknown) *L. infrafrenata*. Conditions were overcast (shade temperature 24°C) and there had been rain the previous evening. The pair was encountered sitting stationary on a wet semi-secluded stone within the spray-zone of a small cascade of Polly Creek in the Seymour Range (60 m elev.) near the township of Innisfail (146.02917°E, 17.499444°S). The male *L. serrata* had a firm grasp around the chest of the *L. infrafrenata*. The eyes of the *L. serrata* were partially retracted into their sockets (which is typical for the genus when at rest) while those of the *L. infrafrenata* were not and the transparent eye-coverings were half-open. The pair was observed at close range for a period of ca. 15 min. during which time there was no

FIG. 1. Male *Litoria serrata* in amplexus with a small adult *Litoria infrafrenata*.

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

movement and they were flash photographed (Fig. 1). Although the pair was briefly manipulated, they remained in amplexus and both frogs were quite unresponsive. The pair was observed ca. two hours later in the same position. As both species are nocturnal, it seems likely that amplexus was initiated the previous evening when both were presumably active. The timing of this observation coincided with the start of the breeding season of *L. serrata* in the local area.

GRANT STEPHEN TURNER, PO Box 2035, Innisfail, Queensland, Australia 4860; e-mail: g.s.turner@hotmail.com.

***PHYSALAEMUS BILIGONIGERUS*. BURROW USE.** Burrows provide an amenable environment for anurans; they have cooler temperatures and higher moisture as compared to surface conditions (Franz 1986. *In* Jackson and Bryant [eds.], The Gopher Tortoise and its Community. Proceedings of the 5th Annual Meeting of the Gopher Tortoise Council, pp. 16–20. Florida State Museum, Gainesville). Cei (1980. Monitore Zool. Ital. Monogr. 2:74–75) reported that the anurans of the Gran Chaco often seek shelter in burrows of the Vizcacha (*Lagostomus maximus*; Rodentia: Chincillidae) but only listed Oven Frogs (*Leptodactylus bufonius*) and Coralline Frogs (*L. laticeps*) as occupants.

On 9 Feb 2011 at 2100 h, I observed a frog emerging from an entrance of a *L. maximus* burrow in the Isoceño community of Kuaridenda (19.17°S, 62.53°W; WGS 84), Cordillera Province, Department of Santa Cruz, Bolivia. I captured the frog and confirmed it to be a female *Physalaemus biligonigerus*. When the frog was released, it re-entered the burrow, emerging again ca. 10 min. later. The frog was not disturbed when it emerged the second time and proceeded to hop in the direction of a temporary pond that was ca. 30 m away. I also observed multiple *L. bufonius* utilizing these same sets of burrows. This observation confirms an additional anuran species as an occupant of *L. maximus* burrows.

Anurans of the Gran Chaco possess many strategies to limit water loss. Examples include coating their skin with waxy lipids (e.g., *Phyllomedusa sauvagii*; Shoemaker et al. 1972. Science 175:1018–1020) or forming a cocoon for aestivation (*Lepidobatrachus llaenis*; McClanahan et al. 1976. Copeia 1976:179–185). Those anurans, like *P. biligonigerus*, lack extreme physiological adaptations to limit water loss and may utilize these burrows as refuge from the environmental stress of desiccation. A more intensive survey of these burrows may yield a more complete list of anuran burrow occupants.

Funding for this trip was provided by the National Science Foundation's Graduate Research Fellowship Program.

CHRISTOPHER M. SCHALK, Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, Texas 77843-2258, USA; e-mail: cschalk@tamu.edu.

***PHYSALAEMUS BILIGONIGERUS*. PREDATION.** *Physalaemus biligonigerus* is probably a complex of more than one species, and is known from northern and central-western Argentina, adjacent Bolivia, Paraguay, Uruguay, and southern and central Brazil. It is common throughout its range and occurs from sea level to 1400 m elev. It occupies grasslands near temporary and permanent lentic water where it breeds. Males call from the edge or from within the water, and the eggs are deposited in spherical foam nests that float on top of the water. It is able to adapt to anthropogenic disturbance, and is not generally considered threatened. However, the species is threatened in Argentina by the destruction of Chaco habitat for agriculture and wood extraction, and land and water pollution caused by agrochemical runoff. Taxonomic studies are needed to resolve the status of different populations that might represent different species (Kwet et al. 2004. *In* IUCN 2010. IUCN Red List of Threatened Species. Version 2010.4. <www.iucnredlist.org>).

This observation occurred near Fazenda Pinhal (30.2199°S, 50.2814°W), near the town of Palmares do Sul (Rio Grande do Sul, Brazil). This area is adjacent to the town of Pinhal and is coastal plain habitat. The region is largely urbanized and agricultural. During the night of 17 Jan 2010 we witnessed predation of *P. biligonigerus* by a young Wolf Fish, *Hoplias* sp., ca. 10 cm long. The frog was attacked on the bank of a slow moving, artificial stream. The Wolf Fish grabbed the frog by the back, and the frog instantly inflated its body; this caused the Wolf Fish difficulty in swallowing the frog as the inflated body of the frog made it difficult for the Wolf Fish to immerse underwater. However after ca. 10 minutes the Wolf Fish succeeded in swallowing the frog and swam away.

EMILIANO UTERMOHL DE QUEIROZ, Programa de Pós-Graduação em Ecologia, Laboratório de Zoologia, Universidade Regional Integrada do Alto Uruguai e das Missões – URI, Campus de Erechim, Av. Sete de Setembro, 1621, Cx. Postal 743 Cep 99700-000, Erechim, RS, Brazil; e-mail: emiliioutermohl@hotmail.com.

***PHYSALAEMUS PUSTULOSUS* (Tungara Frog). DIET.** *Physalaemus pustulosus* occurs in northern South America and throughout much of the lowland tropical forests of Middle America (Ryan 2010. *In* M. Breed and J. Moore [eds.], Encyclopedia of Animal Behavior, pp. 453–461. Academic Press, Oxford). Ryan (1985. The Túngara Frog: A Study in Sexual Selection and Communication. Univ. Chicago Press, Chicago, Illinois. 246 pp.) reported that *P. pustulosus* eats primarily termites, in addition to ants, mites, dipterans, and snails; although no detailed information exists on the food habits of this species. Herein we provide data on the diet of *P. pustulosus* from Reserva Rio Manso (5.666°N, 74.77416°W; ca. 220 m elev.), municipality of Norcasia, departament of Caldas, Colombia.

We examined the diet of *P. pustulosus* by stomach-flushing 78 individuals, sampled by GGD and SEL from 12–20 May 2010, between 1900 and 2200 h, around ponds in pasture lands. We identified each prey item to order or family, and measured the length and width of each item using manual calipers (to nearest 0.1 mm). We estimated prey volume using the formula for a prolate spheroid.

TABLE 1. Types of prey in the diet of *Physalaemus pustulosus* from Reserva Rio Manso, Norcasia, Caldas, Colombia. Volume in mm^3.

Prey	Number (%)	Volume (%)	Frequency of occurrence
Arachnida			
Acari	102 (9.6)	13.2 (0.52)	15

Chilopoda	4 (0.4)	2.9 (0.11)	2
Mollusca	1 (0.1)	5.6 (0.22)	1
TOTAL	1061	2520.3	

Of 78 individuals examined, 46 (58.9%) contained prey. These individuals ranged from 17.9–33.5 mm SVL (mean 26.01 ± 3.2). The diet consisted mainly of arthropods although mollusks were also present (Table 1). Insects (seven orders and 19 families, and larvae) and mites were the most important prey. Termites were dominant in the diet, representing 59.4% of the total number and 96.5% of the volume. Ants were also important, but consumed in less proportion (18.8% and 1.54%, respectively). Other prey groups were not as evident, with values below 9.6% total number and below 0.52% volume).

Duellman (1978. Univ. Kansas Mus. Nat. Hist. Misc. Pub. 65:1–352), Parmelee (1999. Sci. Pap. Nat. Hist. Mus. Univ. Kansas 11:1–59), and Menéndez-Guerrero (2001. Ecología Trófica de la Comunidad de Anuros del Parque Nacional Yasuní en la Amazonía Ecuatoriana. Pont. Univ. Catol. Ecuador. 173 pp.) reported that other *Physalaemus* species, e.g., *P. freibergi* and *P. petersi*, consume a lot of termites, up to 99% both numerically and volumetrically, and very small quantities of other prey such as Coleoptera, Hymenoptera, Dermaptera, Hemiptera, and Arachnida.

Frogs in the genus *Physalaemus* has been reported as active foragers, usually feeding on small and aggregated prey (Rodrigues et al. 2004. Rev. Esp. Herpetol.18:19–28), and proposed as a termite specialist (Duellman 1978, *op. cit.*; Vitt and Caldwell 1994. J. Zool. [Lond.] 234:463–476). Because of the large quantities of termites found in this work, we suggest that *P. pustulosus* in this region could be considered a termite specialist, and that the low values exhibited for other prey items might be due to accidental ingestions (Rodrigues et al. 2004, *op. cit.*).

We are grateful to A. M. Jaramillo and J. H. Castaño for logistic help in the Reserva Privada Riomanso; F. Vallejo and M. Salgado helped identify the prey items. Funding for fieldwork was provided by the Universidad de Caldas at Manizales.

***RAORCHESTES MENGLAENSIS* (Mengla Small Treefrog). COLORATION.** *Raorchestes menglaensis* is a data deficient species. All information for the species is based on 10 individuals that were collected at one site in Zhushihe, Mengla county, Xishuangbanna prefecture, Yunnan province, China at 900 m elev. (Kou 1990. *In* Zhao, E.-M. [ed.], From Water onto Land. China Forestry Press, Beijing). During breeding surveys on 26 June 2009, we encountered a single individual in the Xishuangbanna Tropical Botanic Garden. The frog was found at night during a light rain, calling on a leaf ca. 0.4 m above ground. There was no standing water or streams anywhere nearby, further suggesting this species may breed via direct development. The individual was collected and held overnight for photographing. At night, the frog was largely tan in color with irregular darkened areas and faint banding visible on the hind limbs. The following morning the frog was dark brown to nearly black with light gray specks (Fig. 1).

During three months of weekly breeding surveys, we only saw *R. menglaensis* once. However, other individuals were heard calling on several occasions. This is likely a rare species in need of conservation attention given that its habitat is experiencing significant land use change (Li et al. 2007. Biodiversity and Conservation 16:1731–1745).

Photo vouchers documenting the coloration were deposited in the University of Wisconsin Zoology Museum (light coloration: UWZM V.20187, dark coloration UWZM V.20188). We thank Xishuangbanna Tropical Botanic Garden for access to breeding areas. Funding was provided by NSF DGE-0549369 and Fulbright.

FIG. 1. On left, *Raorchestes menglaensis* at night; on right *R. menglaensis* during the day. The same individual is depicted in both photos.

DEVIN EDMONDS, Amphibian Care, 5101 Golden Leaf Trl., Madison, Wisconsin 53704, USA (e-mail: devin@amphibiancare.com); **JOCELYN E. BEHM,** 430 Lincoln Drive, Madison, Wisconsin 53706, USA.

***RHINELLA MARINA* (Cane Toad). PREDATION.** *Rhinella marina* is a widely distributed toad; in Mexico it is found in the southern region, and along the Atlantic and Pacific versants (Oliver-López et al. 2009. La Familia Bufonidae en México. UNAM, CONABIO, México. 139 pp.). Here we report on the first case of predation of a Cane Toad by the Barn Owl (*Tyto alba*), in the green areas of Instituto Tecnológico del Valle de Oaxaca, in the locality of Nazareno, municipality of Santa Cruz Xoxocotlán, Oaxaca, Mexico (17.0207°N, 96.7673°W; 1565 m elev.). The area is surrounded by remnants of tropical dry forest and arid tropical scrub, which have been replaced extensively by corn crops. Individuals of *T. alba* were observed while they were perching on palm trees, where the pellets of this species were collected. In one of these, we found a partly digested *R. marina* (ca. 132 mm SVL; Fig. 1). This was not in the typical pellet form; however, we were able to confirm ingestion by the owl by the presence of three rodent lower jaws that were associated with the partly digested *R. marina*. This partial digestion may be due to the parotoid glands of *R. marina*, which secrete toxins that are utilized for defense, forcing it to be regurgitated, along with other prey.

Predation on amphibians by *T. alba* has been documented elsewhere (Hernández-Muñoz and Mancina 2011. Rev. Mex. Biodiv. 82:217–226; Wells 2007. The Ecology and Behavior of Amphibians. Univ. Chicago Press, Chicago, Illinois. 1148 pp.), but the only two papers we found that mentioned a toad in the diet of *T. alba* are those of Arredondo and Chirino (2002. El Pitirre 15:16–24) who cited the species *Peltaphryne empusa* in Cuba, and Morales-Hernández (1997. Análisis de los Hábitos Alimenticios de la Lechuza *Tyto alba* en la Población de Chichicasco, Estado de México. Unpubl. BS thesis. BUAP, Puebla, México), who found an unidentified toad in the cave of Agustín Lorenzo in San Pedro Chichicasco, State of Mexico, Mexico. However, this is the first report of *R. marina* in the diet of *T. alba*.

FIG. 1. Partly digested *Rhinella marina*, found in a pellet of the Barn Owl (*Tyto alba*), in Santa Cruz Xoxocotlán, Oaxaca, Mexico.

***RULYRANA OREJUELA* (Orejuela Glass Frog). PREDATION.** Spiders commonly prey on amphibians. Menin et al. (2005. Phyllomedusa 4[1]:39–47) provided an extensive review of spiders preying on amphibians in the Neotropics. Predators belong to several species of spiders, especially within the families Ctenidae, Lycosidae, Pisauridae, Sparissidae, and Theraphosidae. Hayes (1983. Biotropica 15:74–76) reported predation by spiders *Cupiennius* sp. (Ctenidae) on two species of glass frogs: *Hyalinobatrachium fleischmanni* and *Espadarana prosoblepon*. Herein, we report predation of *Rulyrana orejuela* by a spider of the family Clubionidae. This event was observed in an area at the southern border of Reserva Ecológica Cotacachi Cayapas, Provincia de Imbabura, northwestern Ecuador (0.33101°N, 78.93152°W; 670 m). The general locality includes a mixture of secondary and primary forests in the Low Montane Evergreen Forest. We observed a female *Clubiona* sp. preying on *Rulyrana orejuela* on 31 Oct 2009 at 2325 h on the Aguas Verdes stream. At the site, we observed at least three additional juveniles and two adult *R. orejuela*. The genus *Clubiona* was recorded only recently from Ecuador (Yánez-Muñoz and Cisneros-Heredia 2008. Check List 4[1]:50–54). The predation occurred on a dark night with cloudy sky and air temperature averaging 24°C. The spider (cephalothorax and abdomen length CAL = 14.5 mm) and the *R. orejuela* (SVL = 13.9 mm) were located over a leaf of *Selaginella* sp. at about 150 cm above the water surface of the stream, near a rock (1.5 m diam) in midstream. This large rock divided the stream into two parts and formed a small island with herbaceous vegetation, branches, and trunks. The stream had a depth of 25 cm and a width of 7 m. When first sighted the spider was about 10 cm from a dead juvenile *R. orejuela*. After about 5 minutes the spider was seen over the frog with its chelicerae embedded in the frog's body. About 80 cm away we found a nest of the spider with the male inside (CAL = 10.9 mm). The cone-shaped nest was built with a leaf of plant belonging to the Araceae. The nest had a depth of 81.4 mm (inner maximum diameter of nest entrance = 13.1 mm.)

PHOTOS BY L. A. COLOMA

FIG. 1. Female *Clubiona* sp. preying on a juvenile *Rulyrana orejuela*.

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

FIG. 2. Lateral (left) and dorsal (right) views of the nest of *Clubiona* sp. The male spider is visible at right photo.

Spiders of the genus *Clubiona* are small and are characterized by building their nests on the soil with dry leaves, though sometimes their nests are built with live green leaves. In general, they are hunters and specialize in hunting insects around their nests. Austin (1984. S. Austr. J. Arachnol. 1-2:87–104) reported the main prey of *C. robusta* were Hymenoptera, Coleoptera, and Heteroptera. The prey of *C. cycladata* mostly comprised the groups; Heteroptera, Hymenoptera, Araneae, and Coleoptera. Pollard (1984. J. Arachnol. 11:323–326), discussed oophagy in *C cambriggei*. However, this is the first report of a female *Clubiona* sp. eating a *R. orejuela*.

Voucher specimens were deposited at Museo de Zoología of Pontificia Universidad Católica del Ecuador (QCAZ 48616 *R. orejuela* and QCAZ uncatalogued spider).

DIEGO ALMEIDA-REINOSO (e-mail: diegoalmeida@otonga.org) and **LUIS A. COLOMA** (e-mail: lcoloma@otonga.org), Centro Jambatu de Investigación y Conservación de Anfibios, Geovanni Farina 566 y Baltra, San Rafael, Quito, Ecuador.

TESTUDINES — TURTLES

***CHELYDRA SERPENTINA* (Snapping Turtle). GROWTH RATES.** Standard carapace length (SCL) growth rates of adult *Chelydra serpentina* have been reported for Iowa, USA (Christiansen and Burken 1979. Herpetologica 35:261–266), and Ontario, Canada (Brown et al. 1994. J. Herpetol. 28:405–410). In Iowa, Christiansen and Burken (*op. cit.*) reported 4.4% growth for one *C. serpentina* re-captured after 11 months. Brown et al. (*op. cit.*) reported mean annual growth of 1.12% (N = 53) and 0.26% (N = 40) for adult female *C. serpentina* at two separate sites in Ontario, Canada.

On 25 May 2011 and 06 July 2011, within the Blood River and Panther Creek, Calloway Co., Kentucky, USA, we re-captured two *C. serpentina* initially marked with metal cattle tags on 14 May 2004 and 28 May 2004. Initial SCL measurements were 240 mm and 231 mm, and final SCL measurements were 315 mm and 277 mm respectively. Percent SCL growth for these two turtles was 3.4% and 2.4% annually, over a 7-year period. Two previous studies detail regionally specific age estimates for *C. serpentina*

based on carapace length (Christiansen and Burken, *op. cit.*; Galbraith et al. 1989. Copeia 1989:896–904). Based on these studies, the two Kentucky *C. serpentina* were captured at approximately 15–16 years of age (based on Ontario data) or between 11–12 years of age (Iowa); however, these may be over-estimates considering Kentucky's warmer climate and longer growing season compared with Iowa and Ontario.

Growth rates for periods exceeding five years have rarely been reported for *C. serpentina*. The 3.4% and 2.4% annual growth rates for two *C. serpentina* in Kentucky fall within the upper end of the range of previously reported annual growth rates for *C. serpentina* (0.26%–4.4%). These data are consistent with previous studies (Ligon and Lovern 2009. Chelon. Cons. Biol. 8:74–83; Parmenter 1980. Copeia 1980[3]:503–514) demonstrating a relationship between warmer water temperatures and increased annual growth rates of turtles.

BARNARD** (e-mail: jim.barnard@ky.gov), Kentucky Department of Fish and Wildlife Resources, 1 Sportsman's Lane, Frankfort, Kentucky 40601, USA; **HEATHER VENTER**, 4450 Bondarenko Road Keystone Heights, Florida 32656, USA (e-mail: heather_venter@yahoo.com).

***GOPHERUS AGASSIZII* (Desert Tortoise). COHABITATION WITH AMERICAN BADGER.** American Badgers (*Taxidea taxus*) are known predators of juvenile and adult Desert Tortoises as well as their nests (Berry and Duck 2010. Answering Questions About Desert Tortoises: a Guide for People Who Work with the Public. Desert Tortoise Council, Ridgecrest, California. Available online at <http://www.deserttortoise.org/answeringquestions/index.html>). Despite this fact, on 8 August 2011, we observed a badger sharing a caliche cave retreat with an adult male Desert Tortoise in southern Nevada. The badger was seen peering out of the cave before retreating, upon which time some "shuffling" was heard and the tortoise appeared at the cave entrance, apparently unharmed, and proceeded to sit just inside the mouth of the cave. As the tortoise was part of a radio-tracking study, we relocated it a week later and it remained alive and healthy. Though badgers will occasionally kill Desert Tortoises, this observation suggests that they may, at least temporarily, share desert retreat sites with tortoises without antagonistic or predatory behavior.

This research is supported by financial assistance from the U.S. Fish and Wildlife Service, Desert Tortoise Recovery Office (Reno, Nevada, USA).

***KINOSTERNON BAURII* (Striped Mud Turtle). HABITAT AND AERIAL BASKING.** Reported Striped Mud Turtle habitats include lentic bodies of water such as canals, Carolina bays, ponds, swamps, slow-moving streams, and sloughs (Ernst and Lovich 2009. Turtles of the United States and Canada. Johns Hopkins Univ. Press, Baltimore, Maryland. 827 pp.). Observations of this species in riverine systems are rare. Norman (1989. Catesbeiana 9:9–14; M. Norman, pers. comm.) noted this species' (originally reported as *K. subrubrum*, see Mitchell 1994. The Reptiles of Virginia. Smithsonian Inst. Press, Washington, DC. 352 pp.) occurrence in the Blackwater River in southeastern Virginia but did not elaborate on whether captures were in the mainstem or in associated streams and swamps. Only 4 of 2552 turtles captured by Huestis and Meylan (2004. Southeast. Nat. 3:595–612) in the Rainbow River, Marion Co., Florida, were *K. baurii*. Johnston et al. (2011. Florida Sci. 74:126–133) reported two *K. baurii* in the Santa Fe River (Alachua and Columbia counties, Florida) but speculated that those turtles had immigrated to the river from surrounding floodplain swamps which had dried due to prevailing drought conditions.

During May 2007–July 2011, we captured by hand and with baited hoop traps 105 *K. baurii* in the mainstem and associated springs and spring runs of the Santa Fe River. Of these, 9 were caught in the mainstem and 96 were caught in springs and their associated outflow runs adjacent to the river. All river captures were in areas with submerged, emergent, or floating aquatic vegetation (Tapegrass [*Vallisneria americana*], Indian Swampweed [*Hygrophila polysperma*], Hydrilla [*Hydrilla verticillata*], Water Hyacinth [*Eichhornia crassipes*]), or snags. All individuals in the mainstem were adults. Our observations confirm the occurrence of a *K. baurii* population associated with the Santa Fe River mainstem and strengthen the known association between *K. baurii* and lotic habitats.

In addition, we observed five instances of daytime aerial basking by *K. baurii* along the banks of the Santa Fe River and associated spring runs. One juvenile was basking on a leaf overhanging the water and two adult males were on tree limbs (< 10 cm above water) in Blue Spring run, Gilchrist Co. (29.831041°N, 82.681915°W) on 10 August 2009 and 27 March and 4 April 2011, respectively. One adult (unknown sex) was basking on exposed roots along the margin of the mainstem at Rum Island Park, Columbia Co. (29.833143°N, 82.678346°W) on 16 March 2011. One adult male was basking on a small (14 cm diam) piece of limestone 0.28 km downstream from the Hwy. 441 bridge in High Springs, Alachua Co. (29.851967°N, 82.611310°W) on 23 March 2011. All observations were between 1100 and 1700 h. Most observations of these bottom-walkers occur when they are in shallow water or as they walk across the landscape (Ernst and Lovich 2009, *op. cit.*, Wilson et al. 2006. *In* P. A. Meylan [ed.], Biology and Conservation of Florida Turtles, pp. 180–188. Chelon. Res. Monogr. 3). Although aerial basking has been reported for other species of kinosternids, e.g., *K. subrubrum* (Ernst and Lovich 2009, *op. cit.*), *Sternotherus carinatus* (Lindeman 1996. Herpetol. Nat. Hist. 4:23–34), *S. minor* (Carr 1952. Handbook of Turtles. The Turtles of the United States, Canada, and Baja California. Cornell University Press, Ithaca, New York. 542 pp.)), and *S. odoratus* (Ernst 1986. J. Herpetol. 20:341–352), there appears to have been no published documentation of this behavior in *K. baurii* (Wilson et al. 2006. *op. cit.*; D. Wilson, pers. comm.). Basking behavior by *K. baurii* in the Santa Fe River population may have a thermoregulatory function, as we recorded air temperatures 1.7–3.1°C greater than water temperatures. Basking may also be related to ectoparasite removal, as suggested by a statistically significant difference in leech (*Placobdella* sp.) load between basking adult males (mean = 37.3 leeches/turtle, SD = 45.6, range = 10–90, N = 3) and non-basking adult males (mean = 1.9 leeches/turtle, SD = 3.0, range = 1–12, N = 43) (Mann-Whitney Rank Sum Test, U = 2.500, p = 0.004). These suggested causes of aerial basking in riverine environments need to be tested with other observations of basking *K. baurii* in lotic as well as lentic habitats.

JOSEPH C. MITCHELL, P.O. Box 2520, High Springs, Florida 32655, USA (e-mail: dr.joe.mitchell@gmail.com); **GERALD R. JOHNSTON**, Department of Natural Sciences, Santa Fe College, Gainesville, Florida 32606 USA (e-mail: jerry.johnston@sfcollege.edu).

***STERNOTHERUS CARINATUS* (Razor-backed Musk Turtle). ECTOPARASITES.** To our knowledge, there have been no previous published reports of leeches infesting *Sternotherus carinatus*. Herein we report a new host record for a leech species found on this turtle.

Three adult *S. carinatus* were collected by dipnet on 5 June 2001 from the Caddo River off St. Hwy. 7, Clark Co., Arkansas, USA (34.176523°N, 93.07121°W). Turtles were returned to the laboratory and (because vouchers were required for parasitological surveys) they were killed with an overdose of sodium pentobarbital (Nembutal®), and examined for leeches and gastrointestinal helminth parasites. No helminths were found but one (33%) was infested with 15 leeches attached in the corners of its limbs. They were removed and placed in a vial containing 70% ethanol. These were subsequently identified as juveniles of *Placobdella multilineata* Moore, 1953. Voucher specimens of leeches were deposited in the Invertebrate Zoology Collection of the Department of Invertebrate Zoology, National Museum of Natural History (USNM), Smithsonian Institution, Washington, D.C. as USNM 2057950. Host vouchers were deposited in the Texas A&M University-Texarkana Herpetological Collection (TAMUT), Texarkana, Texas as TAMUT 1005–1006.

This leech is a relatively common blood-feeding species on amphibians and reptiles. Previously reported turtle hosts include the Eastern Snapping Turtle, *Chelydra serpentina* (Sawyer and Shelley 1976. J. Nat. Hist. 10:65–97; Stone 1976. Southwest. Nat. 20:575–576), Alligator Snapping Turtle, *Macroclemys temminckii* (Saumure and Carter 1998. Herpetol. Rev. 29:98), Yellow-bellied Slider, *Trachemys scripta scripta* (Sawyer and Shelley 1976. J. Nat. Hist. 10:65–97), and Bog Turtle, *Clemmys muhlenbergii* (Saumure and Beane 2001. Herpetol. Rev. 32:38; Saumure and Carter 1998. Herpetol. Rev. 29:98).

This leech has an extensive range in the southern United States, extending northward through the Mississippi River Valley and eastward to the Atlantic coast, including Alabama, Arkansas, Florida, Georgia, Kansas, Illinois, Iowa, Louisiana, Nebraska, North Carolina, Oklahoma, South Carolina, Tennessee, and Texas (Klemm 1982. Leeches (Annelida: Hirudinea) of North America. Environmental Monitoring and Support Laboratory, USEPA-600/3-82-025. Cincinnati, Ohio. 177 pp.). Moser et al. (2006. J. Arkansas Acad. Sci. 60:84–95) reported free-living specimens of *P. multilineata* from Arkansas for the first time in Conway, Jackson, Perry, Randolph, and Van Buren counties, all located north of the Arkansas River Valley; our site reported herein is south of the valley in the Ouachita Mountains.

We thank the Arkansas Game and Fish Commission for a Scientific Collecting Permit issued to CTM and Renn Tumlison for assistance in collecting.

CHRIS T. McALLISTER, Science and Mathematics Division, Eastern Oklahoma State College, Idabel, Oklahoma 74745, USA (e-mail: cmcallister@se.edu); **WILLIAM E. MOSER**, Smithsonian Institution, National Museum of Natural History, Department of Invertebrate Zoology, Museum Support Center-MRC 534, 4210 Silver Hill Road, Suitland, Maryland 20746, USA (e-mail: moserw@si.edu).

***STERNOTHERUS MINOR MINOR* (Loggerhead Musk Turtle). PREDATION.** A large number of likely mammalian, avian, and reptilian predators have been listed for the eggs and juveniles of *Sternotherus m. minor* (Ernst and Lovich 2009. Turtles of the United States and Canada. Johns Hopkins Univ. Press, Baltimore, Maryland. 827 pp.), but invertebrate predators have apparently not been noted, and few predators have been documented for adults of this species. These include Alligator Snapping Turtles (*Macrochelys temminckii*), American Alligators (*Alligator mississippiensis*), and humans (Pritchard 1989. The Alligator Snapping Turtle: Biology and Conservation. Milwaukee Public Mus., Milwaukee, Wisconsin. 104 pp.; Zappalorti and Iverson 2006. *In* P. A. Meylan [ed.], Biology and Conservation of Florida Turtles. Chelonian Res. Monogr. No. 3:197–206). In this note, we describe successful predation on adult *S. minor* by River Otters (*Lutra canadensis*), and attempted predation of a juvenile by an invertebrate.

In two separate observations on 10 and 11 January 2011, we observed an adult River Otter in the process of biting off the head and forelimbs of an adult *S. minor* in the Santa Fe River, 1.15 km downstream from Deer Spring (Gilchrist Co., Florida; 29.84757°N, 82.71074°W, WGS 84). In each instance, the otter set the turtle on a log near shore after eating it; the turtle's rear limbs were still moving a minute later, though most of the internal organs had been consumed. Together with *M. temminckii* and *Alligator mississipiensis* that also occur in the Santa Fe River (G. R. Johnston, pers. obs.), River Otters may be significant predators of *S. minor* and play a role in the population ecology of these turtles in this river system.

On 13 February 2011, we observed a female Giant Water Bug, *Lethocerus americanus* (Belostomatidae), manipulating a prey object as it was anchored on *Hydrilla* stems at the confluence of the Ginnie Spring outflow run with the Santa Fe River in Gilchrist County, Florida (29.83655°N, 82.69942°W, WGS 84). She was gripping a juvenile *S. minor* (34 mm carapace length, 22 mm plastron length, 5.5 g) at a depth of about 3 cm, holding the turtle by its anterior carapace and probing the shell with her proboscis. She had not yet penetrated soft tissue when discovered but would likely have killed and eaten the turtle had we not intervened. The turtle was marked and released. This is the first report of attempted predation of *Sternotherus minor* by an invertebrate and apparently the first such attempt reported for the genus.

Matthew Kail aided in the field observation.

JOSEPH C. MITCHELL, P.O. Box 2520, High Springs, Florida 32655, USA (e-mail: dr.joe.mitchell@gmail.com); **GERALD R. JOHNSTON**, Department of Natural Sciences, Santa Fe College, Gainesville, Florida 32606, USA (e-mail: jerry.johnston@sfcollege.edu).

***TRACHEMYS ORNATA* (Ornate Slider). HATCHLINGS.** *Trachemys ornata* is a middle-sized emydid turtle that ranges from northern Sinaloa and Nayarit to isolated populations in Guerrero and Oaxaca on the Pacific coast of Mexico (Ernst and Barbour 1989. Turtles of the World. Smithsonian Institution Press. Washington, D.C. 313 pp.). There is little published information about the life history and reproduction of this species, other than anecdotal data on clutch size (12–20 eggs) and age of first reproduction (4–8 years) (Moll and Moll 1990. *In* J. W. Gibbons [ed.], Life History of the Slider Turtle, pp. 152–161. Smithsonian Institution Press, Washington, DC).

On 24 May 2005 we recorded hatchling emergence from one nest of 13 eggs located just a few meters away from a road in Playa Linda (17.681028°N, 101.644139°W), a beach resort in the tourist-oriented corridor Ixtapa-Zihuatanejo, in Guerrero, México. The nest had been deposited 25 m away from a small marsh and approximately 70 m from the sea coastline. After the last hatchling emerged, we excavated the nest and found one unhatched (decayed) egg. We measured the surviving hatchlings (N = 12) with a dial caliper (± 0.02 mm). The shell measurements (in mm) are given as: average (± SD, range). Carapace length 37.96 (± 2.58, 34.16–41.81), carapace width 34.72 (± 3.33, 28.77–39.04),

carapace height 18.25 (± 1.20, 16.91–20.71), plastron length 34.74 (± 2.29, 31.72–37.61), and plastron width 24.88 (± 1.23, 22.94–26.54). After measurement, the hatchlings were released at the marsh shore. This clutch size for *T. ornata* was similar to that reported for *T. venusta* (N = 12, 5–22 eggs); however, average hatchling carapace length was larger in *T. ornata* than reported for *T. venusta* (mean = 31.8, 25.0–37.8 mm) (Vogt 1990. *In* Gibbons, *op. cit.*, pp. 162–168).

México; **XÓCHITL AGUILAR MIGUEL**, Centro de Investigación en Recursos Bióticos, Facultad de Ciencias, Universidad Autónoma del Estado de México, Instituto Literario #100, 50000, Toluca, Estado de México, México.

SQUAMATA — LIZARDS

***AMEIVA AMEIVA* (Giant Ameiva). BIFURCATION.** *Ameiva ameiva* is one of the most widely distributed Neotropical lizards, occurring from the Caribbean Islands and Costa Rica to southern Brazil, northern Argentina and the eastern Andes in South America (Vitt and Colli 1994. Can. J. Zool. 72:1986–2008). All teiid lizards are capable of caudal autotomy as a means of predation evasion. Occasionally an additional lateral tail can be produced if the original is broken, but not entirely lost.

On 26 March 2009 during the rescue activities of wildlife from the Project of Integration of São Francisco River (PISF) within the basins of Northeastern Setentrional, we collected an adult *A. ameiva* in the municipality of Sertânia, state of Pernambuco, Brazil (8.086°S, 37.384°W, datum: WGS84; elev. 558 m). The tail of the lizard was bifurcated in the medial region (ca. 35 mm posterior from the cloaca), and one of the regenerated tails was much shorter than the other (Fig. 1). Records of bifurcated tail regeneration have been published for many lizard species (see Kumbar and Ghadage 2011. Herpetol. Rev. 42:94; Mata-Silva 2010. Herpetol. Rev. 41:352–353, and citations therein), and some of these cases show that the bifid or multiple regeneration of tails involve damage to a vertebra. This is presumably what the *A. ameiva* incurred in this report.

The *A. ameiva* (LC 0969) was deposited in the scientific collection of the Centro de Conservação e Manejo de Fauna da Caatinga (CEMAFAUNA-Caatinga/UNIVASF), Petrolina, Pernambuco, Brazil. We thank the Ministério da Integração Nacional for financial support, and the Coordenação de Aperfeiçoamento de Pessoal de Nível Superior (Capes) for the research scholarship granted to ML; IBAMA provided the collecting permits (# 042/2007 and 125.r/2010 Process n° 02001.003112/2007-12).

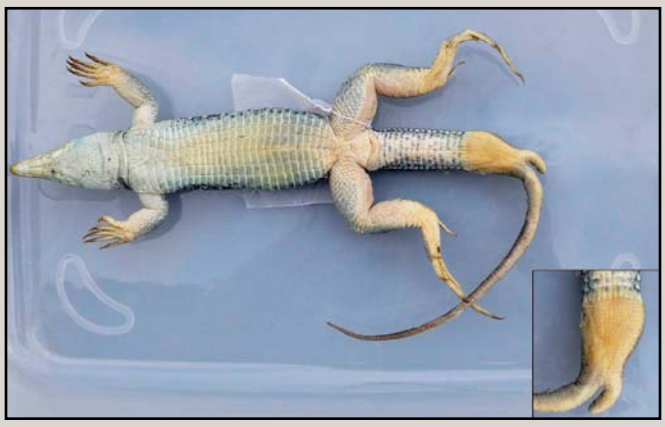

FIG 1. *Ameiva ameiva* (135 mm SVL) with bifurcated tail in the medial region (inset); length of broken tail: 35 mm; length of regenerated tails: 120 mm and 15 mm.

***ANOLIS CAPITO* (Pug-nosed Anole). DIET.** Although some lizards are dietary specialists, most species consume a wide variety of arthropods (Magnusson and Da Silva 1996. J. Herpetol. 27:380–385). Some detailed dietary studies on small lizards in neotropical areas showed relatively few vertebrate prey (e.g., Garnier et al. 1994. J. Herpetol. 28:187–192; Vitt 1991. Can. J. Zool. 69:504–511; Vitt and de Carvalho 1992. Can. J. Zool. 70:1995–2006; Vitt et al. 1993. Can. J. Zool. 71:2391–2400; Vitt et al. 1998. Can. J. Zool. 76:1681–1688; Vitt et al. 1997. Can. J. Zool. 75:1876–1882; Vitt et al. 2001. Copeia 2001:401–412). However, *Neusticurus ecpleopus* (Gymnophthalmidae) includes frog larvae in its diet at an Amazon locality (Vitt et al. 1998. Can. J. Zool. 76:1671–1680) and *Kentropyx striatus* (Teiidae) has been found to have a high proportion of vertebrates, especially frogs, in its diet (Magnuson and Da Silva 1996, *op. cit.*; Vitt and de Carvalho 1992, *op. cit.*). Some other teiids such as *Tupinambis* also are known to consume frogs (Pianka and Vitt 2003. Lizards: Windows to the Evolution of Diversity. Univ. California Press, Los Angeles, California. 333 pp.), but these are large bodied animals. Frogs are consumed by *Anolis* lizards, especially relatively large-bodied species such as *Anolis punctatus* in Brazil (Vitt et al. 2003. J. Herpetol. 37:276–285). Here we provide the first report of frog predation by *Anolis capito*, a small species (SVL = 83–96 mm, females; 78–90 mm, males) (Savage 2002. Amphibians and Reptiles of Costa Rica: A Herpetofauna Between Two Continents, Between Two Seas. University of Chicago Press, Chicago, Illinois. 1056 pp.).

In Costa Rica, *Anolis capito* is found along the Caribbean slope and in the southwestern lowlands, in deeply shaded forest interiors (Leenders 2001. A Guide to Amphibians and Reptiles of Costa Rica. Zona Tropical, Miami, Florida. 305 pp.). It is most frequently observed on the ground or perched low on a trunk 0.25–2 m above the ground (Savage 2002, *op. cit.*). It feeds mainly on spiders, orthopterans, and caterpillars, and often also takes slugs (Savage 2002, *op. cit.*). It also takes small vertebrates such as other anoles (Leenders 2001, *op. cit.*). At 0950 h on 20 October 2001 in Golfito National Wildlife Refuge, Puntarenas Province, SW Costa Rica (8.638611°N, 83.167778°W), we found an adult male (85 mm SVL) *A. capito* eating a Pigmy Rain Frog (*Pristimantis ridens*) (18 mm long). Neither animal was collected. *Pristimantis ridens* is a very common nocturnal forager in low vegetation that often hides in the leaf litter during the day (Savage 2002, *op. cit.*). The two species have overlapping distributions along the Pacific and Atlantic slopes of Costa Rica. We do not know the frequency of predation or the importance of *P. ridens* in the diet of *A. capito*. This is one of relatively few observations of *Anolis* consuming a frog and is the first report of lizard predation on *Pristimantis ridens*.

Observations were made during a field trip of the "Reptiles" course of the School of Biology, University of Costa Rica (UCR).

We acknowledge UCR for support in Golfito and thank W. Eberhardt for his suggestions on the manuscript.

***BRACHYMELES BOULENGERI* (Philippine Slender Skink). DIET.** *Brachymeles boulengeri* is a pentadactyl, semi-fossorial lizard known from Luzon, Polillo, and Marinduque islands in the northern Philippines. Considered a model system for studying the evolution of limb reduction and loss in squamate reptiles, the genus *Brachymeles* possesses species with a full spectrum of body forms, including pentadactyl, non-pentadactyl, and limbless species (Siler and Brown 2011. Evolution doi:10.1111/j.1558-5646.2011.01315.x; Siler et al. 2011. Mol. Phylogen. Evol. 59:53–65). All species are known to burrow in loose soil and rotting logs, making it difficult to observe dietary preferences (Siler and Brown 2010. Herpetol. Monogr. 24:1–54). As a result of their secretive nature, no studies have reported on observed dietary preferences for any species within this unique genus, and it has long been presumed that the diet consists of small invertebrate species. This is the first record of saurophagy for the genus *Brachymeles*.

While conducting fieldwork in the Philippines, we observed a male *Brachymeles boulengeri* (total length = 178 mm; 17.9 g) consume an adult *B. bonitae* head-first. Adult specimens of both species were collected on 7 May 2011, and placed in the same specimen bag during the return trip to base camp Malaboo, Mt. Makiling Forest Reserve, Barangay Bagong Silang, Municipality of Los Baños, Laguna Province, Luzon Island, Philippines (14.13356°N, 121.20447°E, datum: WGS84; elev. 665 m). Between the time of collection and arrival in camp, the individual of *B. boulengeri* consumed the individual of *B. bonitae*. An autotomized tail fragment of the *B. bonitae* specimen was not consumed, and was preserved in 95% EtOH as a tissue voucher. Examination of the stomach contents of the *B. boulengeri* specimen confirmed the ingestion of the smaller species *B. bonitae* (Fig. 1). The *B. boulengeri* specimen, with intact stomach content, and the tail sample of the consumed individual of *B. bonitae*, were preserved and deposited at the Biodiversity Institute, University of Kansas (CDS 5626: *Brachymeles boulengeri*; CDS 5612 [Genetic Sample]: *Brachymeles bonitae*).

FIG. 1. An adult *Brachymeles boulengeri* (above) with dissected stomach contents showing an ingested adult *Brachymeles bonitae* (below) on Mt. Makiling, Luzon Island, Philippines.

***CERCOSAURA SCHREIBERSII*. DIET.** *Cercosaura schreibersii* is a gymnophthalmid lizard with wide geographical distribution in South America that occurs in southeastern Peru, Bolivia, Paraguay, Argentina, Uruguay and southern Brazil (Lema 1994. Comun. Mus. Ciênc. PUCRS, Sér. Zool. 7:41–150). Information concerning the biology of the species is scarce and here we present basic information on diet of this lizard. Data were obtained from analysis of 28 adult individuals of *C. schreibersii* (10 males and 18 females; mean SVL 358 mm ± 32 mm) collected in coastal sand dune environments in Rio Grande, Rio Grande do Sul (32.1654°S, 52.1523°W, sea level), southern Brazil. The contents from stomachs and intestines were analyzed and each prey item was identified to order under a stereomicroscope. The results are presented in Table 1. Aranae were a predominant item in the diet, present in 67.9% of lizard contents and representing 46.3% of total items consumed. The second most important prey were Isopoda, present in 17.9% of lizards and representing 12.2% of the items consumed. Only 10.7% of lizards had no contents in the digestive tract. Our data support preliminary assessments concerning dietary specialization in *C. schreibersii* (Achaval 1984. Bol. Soc. Zool. Uruguay Seg. Epoc. 2:59–62). The consumption of spiders is known for some species of lizards but not as a predominant dietary item (e.g., *Anolis*, *Tropidurus*, and *Ophiodes*; Ávila-Pires 1995. Zool. Verh. Leiden. 1995:3–706; Vitt

TABLE 1. Prey items present in the digestive tracts of 28 adult individuals of *Cercosaura schreibersii* captured in sand dune habitats of southern Brazil.

and Caldwell 1993. J. Herpetol. 27:46–52). Dietary specialization suggests particular adaptation processes highlighting its potential for studying the evolution of foraging habits on lizards. The *C. schreibersii* vouchers (RGRM: 05, 06, 16, 17, 19–37, and 40–45) were deposited in the Coleção Herpetológica Laboratório de Ecologia de Vertebrados Terrestres of Instituto de Ciencias Biológicas, Universidade Federal do Rio Grande. We thank CNPq and Fapergs for financial support and ICMBio by collecting permits.

MAURÍCIO B. DOS SANTOS, CINDY MARQUES, DAIANE CARRASCO, LETÍCIA V. DO NASCIMENTO, and **ALEXANDRO M. TOZETTI,** Laboratório de Ecologia de Vertebrados Terrestres, Instituto de Ciencias Biológicas, Universidade Federal do Rio Grande, Av. Itália, km 8, Rio Grande, RS, Brazil (e-mail: alexandro.tozetti@gmail.com).

***CROTAPHYTUS BICINCTORES* (Mojave Black-collared Lizard). ENDOPARASITES.** *Crotaphytus bicinctores* occurs in xeric rocky habitats in southeastern and northeastern California, parts of Arizona, Oregon, Idaho, Utah, and much of Nevada (McGuire 1996. Bull. Carnegie Mus. Nat. Hist. 32:1–143.). To our knowledge, there are no reports of helminths for this species. The purpose of this note is to establish the initial helminth list for *C. bicinctores*.

One nematode was found in the body cavity of one female *C. bicinctores* (SVL = 88 mm) collected October 1962 at Pisagh Crater, San Bernardino Co., California, USA (34.746378°N, 116.37557°W, WGS84; elev. 753 m) and deposited in the herpetology collection of the Natural History Museum of Los Angeles County (LACM), Los Angeles, California, USA as LACM 21651. The nematode was cleared in a drop of glycerol on a glass slide, cover-slipped, and identified as an adult female *Thubunaea iguanae*. It was deposited in the United States National Parasite Collection, Beltsville, Maryland as USNPC 104864.

Thubunaea iguanae is a common stomach parasite of lizards from the southwestern United States and Mexico (McAllister et al. 2008. Comp. Parasitol. 75:241–254) and has been found in the congeners *C. collaris* (McAllister et al., *op. cit.*) and *C. vestigium* (Goldberg and Bursey 2010. Herpetol. Rev. 41:353). It also occurs in colubrid snakes (Goldberg and Bursey 2001. Bull. So. California Acad. Sci. 100:109–116). It is in the family Physalopteridae, species of which utilize insect intermediate hosts (Anderson 2000. Nematode Parasites of Vertebrates. Their Development and Transmission, 2nd ed. CABI Publishing, Oxfordshire, UK. 650 pp.). *Crotaphytus bicinctores* is a new host record for *Thubunaea iguanae*.

We thank Christine Thacker (LACM) for permission to examine *C. bicinctores*.

STEPHEN R. GOLDBERG, Department of Biology, Whittier College, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu); **CHARLES R. BURSEY,** Department of Biology, Pennsylvania State University, Shenango Campus, Sharon, Pennsylvania 16146, USA (e-mail: cxb13@psu.edu).

***CTENOSAURA SIMILIS* (Gray's Spiny-tailed Iguana) and *IGUANA IGUANA* (Green Iguana). CARRION FEEDING.** Adult *Ctenosaura similis* and *Iguana iguana* are primarily herbivorous (Hirth 1963. Ecology 44:613–615; Krysko et al. 2008. Florida Sci. 72:48–58; Montanucci 1968. Herpetologica 24:305–315; Rand et al. 1990. J. Herpetol. 24:211–214). However, *C. similis* will opportunistically prey upon small vertebrates (summarized by Krysko et al., *op. cit.*), and an adult female ate a piece of meat from a discarded roast beef sandwich (Meshaka et al. 2004. The Exotic Amphibians and Reptiles of Florida. Krieger Publ. Co., Malabar, Florida. 155 pp.). In Panama, *Iguana iguana* purportedly will eat

FIG 1. An adult female *Iguana iguana* (foreground) and adult male *Ctenosaura similis* (background) feeding on the carcass of an *Odocoileus virginianus clavium* along with *Cathartes aura* on Big Pine Key, Monroe Co., Florida, USA.

human excrement (Swanson 1950. Herpetologica 6:187–193), and two adults were observed feeding upon the carcass of a putrefying opossum (probably *Didelphis marsupialis*) along with two Turkey Vultures (*Cathartes aura*) (Loftin and Tyson 1965. Copeia 1965:515).

In pine rockland habitat on Big Pine Key, Monroe Co., Florida, USA, a Wildgame© passive infrared camera was positioned near carcasses of three Key Deer (*Odocoileus virginianus clavium*) from 16–20 May 2011. As many as three iguanas were caught in a single image, and at least four different iguanas were recorded. The camera was set to 30-sec intervals and recorded 59 images of *I. iguana* and 20 images of *C. similis* between 0928 h and 1738 h. The longest feeding period recorded was >5 min (N = 2), and the shortest was <30 sec. *Cathartes aura*, *C. similis*, and *I. iguana* were recorded feeding together in multiple images (Fig. 1). Some images seemed to indicate that a large male *C. similis* was able to take possession of the carcass from *C. aura* for short periods. Biologists have noted high numbers of *I. iguana* at the deer carcass disposal site since at least 2009 but had not previously witnessed carrion feeding.

***DIPSOSAURUS CATALINENSIS* (Santa Catalina Island Desert Iguana). PREDATION.** Little information has been reported about the natural history of Santa Catalina Island Desert Iguana (Grismer 2002. Amphibians and Reptiles of Baja California, Including its Pacific Islands and the Islands in the Sea of Cortes. University of California Press, Berkeley and Los Angeles. 399 pp.). The rattlesnake *Crotalus catalinensis* has been reported as a predator of *D. catalinensis* (Avila-Villegas et al. 2007. Copeia 2007[1]:80–84), but to date, reports of avian predation have not been documented for this species. We report here evidence of bird predation on *Dipsosaurus catalinensis* by the Loggerhead Shrike (*Lanius ludovicianus*), which preys on a wide variety of vertebrates including reptiles (mainly lizards) (Lefranc 1997. Shrikes: A Guide to the Shrikes of the World. Yale University Press, New Haven and London. 192 pp.).

On 3 April 2011 at 1450 h, we saw a shrike fly past us with a lizard in its bill. It perched on an Adam's Tree (*Fouquieria diguetii*) at 1.55 m off the ground, on Santa Catalina Island, Gulf of California, Mexico (25.60536944°N, 110.7747917°W, datum WGS 84; elev. 13 m). As the bird settled, it pierced the iguana's dorsal skin with a thorn, leaving it hanging on the branch and still alive. As we approached, the shrike moved to another branch and then flew away. We removed the iguana and measured it after taking some photographs. The juvenile *D. catalinensis* measured 87 mm SVL and weighed 13 g. After the measurement the iguana was returned to the same branch as first positioned by the shrike. After we moved away several minutes later, the shrike came back and took the iguana elsewhere to continue consumption.

GEKKO MONARCHUS **(Warty House Gecko). BIFURCATION.** *Gekko monarchus* is a large house gecko from Southeast Asia found primarily in southern Thailand, the Philippines, the Malay Peninsula, Borneo, Java, Sumatra, and Indonesia. It occupies forest edges as well as human habitations and has been known to nest communally, with over 50 eggs discovered in a single area (Das 2010. A Field Guide to the Reptiles of South-east Asia. New Holland Publishers, London. 376 pp.). Near an electric light on 1 August 2011 at 2330 h, we observed a small (~60 cm SVL) individual *G. monarchus* with a bifid tail on an interior support beam of a wooden longhouse structure near Batang Ai National Park in Sarawak, Borneo (1.159064°N, 111.925263°E). The tail was bifurcated for roughly 2 cm at the posterior end, with one tail tip roughly 0.5 cm longer than the other. Although we observed neither predation nor intraspecific agonistic interactions, many of the other individuals found on this and nearby structures were missing limbs or had regenerated or damaged tails.

ALEXANDER D. McKELVY (e-mail: amckelvy@gc.cuny.edu) and **ASHLEY O. McKELVY,** CUNY Graduate Center and Biology Department, College of Staten Island, Staten Island, New York 10314, USA (e-mail: aozelski@gc.cuny.edu).

HELODERMA SUSPECTUM **(Gila Monster). INJURY FROM NON-NATIVE SEED.** The deserts of the southwestern U.S. have been invaded by a multitude of non-native species of grasses and noxious weeds. Their establishment has had significant ecological effects on the landscape, including increased fire regime, competition with native flora for water and growing space, as well as injurious effects on wildlife. Among these invasive species, Red Brome (*Bromus madritensis* ssp. *rubens*) has established itself throughout much of the Sonoran Desert. In Arizona, Red Brome typically occurs in soils of low to mid-elevation regions (300–2843 m) in arid and semi-arid desert scrub. It has several modes of seed dispersal, including wind, caching by ants and rodents, and attaching to mobile organisms with the sharp, pointed florets that develop when it senesces (Esque and Schwalbe 2002. *In* B. Tellman [ed.], Invasive Exotic Species in the Sonoran Region, pp. 165–194. University of Arizona Press, Tucson, Arizona). The latter trait has been known to injure herbivorous animals that feed on it and predatory animals that forage in stands of it (McCrary and Bloom 1984. J. Wildl. Manag. 48:1005–1008; Medica and Eckert 2007. Herpetol. Rev. 38:446–448). Here I present an observation of Red Brome having attached to a Gila Monster (*Heloderma suspectum suspectum*) in central Arizona, with obvious deleterious effects.

On 22 April 2011, at 1825 h, I (and another observer) encountered an adult *H. suspectum* as it walked in the open on a public trail in a canyon adjacent to Roosevelt Lake in Gila Co., Arizona, USA (33.69575°N, 111.18861°W, WGS 84). The trail was at the north end of the canyon at the base of an east-facing slope. Associated vegetation included Brittlebush (*Encelia farinosa*), Ocotillo (*Fouquieria splendens*), Jojoba (*Simmondsia chinensis*), Flat-top Buckwheat (*Eriogonum fasciculation*), palo verde (*Parkinsonia* sp.), Saguaro Cactus (*Cereus giganteus*), and Red Brome. As I approached the animal it became alert and assumed a defensive position. I observed a grass seed caught in the left eye, and upon capturing the animal for further examination, found that the grass seed was Red Brome. The sharp end of the floret was wedged in the anterior portion of the left eye and had caused severe inflammation, fluid drainage in the form of pus, and the eye partially swelling closed. I proceeded to remove the seed from its eye and released the lizard, after which it quickly retreated under a nearby Jojoba plant.

This incident demonstrates the potential injurious effects of Red Brome on native reptiles. Whether injury caused by Red Brome is a common occurrence in *H. suspectum* is unknown. However, similar instances have been documented in other large desert reptiles such as the (Mojave) Desert Tortoise (Medica and Eckert, *op. cit.*).

I thank K. Freese for field assistance. D. Beck, J. Wynne, and E. Nowak provided comments on earlier versions of this manuscript. This work was conducted under Arizona Game & Fish Scientific collecting permit #SP710162 CLS.

CALEB L. LOUGHRAN, Colorado Plateau Research Station, Northern Arizona University, Applied Research & Development Bldg., Suite 150, Flagstaff, Arizona 86011, USA; e-mail: caleb.loughran@gmail.com.

HELODERMA SUSPECTUM **(Gila Monster). DIET.** *Heloderma suspectum* is a predatory lizard of the southwestern U.S. and adjacent northwestern Mexico that specializes in raiding the nests of lagomorphs, rodents, and ground-dwelling birds (reviewed by Beck 2005. Biology of Gila Monsters and Beaded Lizards. Univ. California Press, Los Angeles and Berkeley. 224 pp.). Though other reptiles have been recorded as prey items (Ortenburger and Ortenburger 1926. Proc. Oklahoma Acad. Sci. 6:101–121), predation on non-egg life stages is a somewhat uncommon occurrence in the literature. Additionally, hatchling birds and adult rodents are rarely seen in the dietary spectra of *H. suspectum* (Beck, *op. cit.*).

From 2004 to 2008 we conducted radio-telemetry on sympatric *H. suspectum, Crotalus cerberus, C. atrox,* and *C. molossus* at Tonto National Monument, Gila Co., Arizona, USA. The site is characterized by steep rocky slopes, bajadas, and dry washes with upland Sonoran desertscrub, with elevations ranging from 695–1230 m. We documented prey use through blunt dissection of scats opportunistically collected when an animal defecated (Quick et al. 2005. J. Herpetol. 39:304–307), as well as regurgitated meals.

Prey use was documented for three *H. suspectum* (two adults, one subadult) by scat analysis. Two scats were collected from two of the adults (one male, one female, both telemetered) and one scat was collected from the subadult (female, not telemetered). One occasion when the subadult female was recaptured,

hairs were removed from her mouth and saved for analysis. Scat dissection/hair analysis revealed five types of prey consumed by the three individuals. The adult male had consumed *Peromyscus eremicus* (Cactus Mouse) and *Callipepla gambellii* (egg fragments and feathers); the adult female consumed *Sylvilagus audubonii* (Desert Cottontail) and an *Aspidoscelis* sp. (whiptail lizard); and the subadult female consumed *Eutamias dorsalis* (Cliff Chipmunk) (represented at separate times by both scat and the hairs in her mouth). In addition to the scat observations, two other feeding observations were made. The subadult female was observed feeding on cottontail pups in a burrow (number unknown) and a third adult (male, telemetered) regurgitated two cottontail pups during surgery while in captivity.

Because *H. suspectum* may consume several individual prey items in a single meal, especially when raiding nests, the number of individual prey items taken in a particular, single feeding event is unknown. Based on size and length of the chipmunk hairs analyzed, they were presumed to be adult hairs; however, because hairs were often damaged after gut passage, ontogenetic characteristics of some hairs may have been distorted. Given the typical nest raiding habits of this predator, the presence of adult mammal hair and feathers in the *H. suspectum* scats may be parental hairs and feathers associated with neonates in the nest. The presence of the *Aspidoscelis* sp. in the scat is unusual but has been previously documented once before (Ortenburger and Ortenburger, *op. cit.*). Based on previous inventories conducted at the Monument, the possible species of *Aspidoscelis* at the site are *A. tigris* (Tiger Whiptail), *A. sonorae* (Sonora Spotted Whiptail), and *A. flagellicauda* (Gila Spotted Whiptail; Albrecht et al. 2007. Vascular Plant and Vertebrate Inventory of Tonto National Monument. OFR 2007-1295. USGS, Southwest Biological Science Center, Sonoran Desert Research Station, Univ. Ariz., Tucson). A possibility for this prey item is opportunistic predation of a whiptail lizard cornered in a burrow (perhaps while it was sleeping) or the *Heloderma* scavenging a dead whiptail lizard.

Support for our research was provided by the National Park Service, the Western National Parks Association, and the J. W. Prather Memorial Scholarship. Assistance was provided by M. Cardwell, E. Dugan, L. Gilmore, H. E. Graham, M. Hamilton, A. Madara-Yagla, K. Nishikawa, J. Schofer, the staff of Tonto National Monument, and numerous volunteers. M. Cardwell, J. Ennen, J. Lovich, P. Salo, C. Spencer, and two anonymous reviewers commented on earlier drafts of this note.

CALEB L. LOUGHRAN (e-mail: caleb.loughran@gmail.com), **ERIKA M. NOWAK** (e-mail: Erika.Nowak@nau.edu), and **ROBERT W. PARKER** (e-mail: parkeranywhere68@hotmail.com), Colorado Plateau Research Station, Northern Arizona University, Applied Research & Development Bldg., Suite 150, Flagstaff, Arizona 86011, USA.

***HEMIDACTYLUS FRENATUS* (House Gecko). PREDATION.** On 28 April 2011 at 2015 h, we observed a Great-tailed Grackle (*Quiscalus mexicanus*) feeding on an adult *Hemidactylus frenatus* on the edge of a window of a house in Sanchez Magallanes, Tabasco, México (18.2888694°N, 93.8716167°W). The next day we made a second observation of a *Q. mexicanus* feeding on another *H. frenatus* at the same location at 0745 h.

This interaction is notable, given that *H. frenatus* is an invasive species native to Asia and the Indo-Pacific that has displaced native species in some regions (Case et al. 1999. Ecology 72:464–477; Cole et al. 2005. Biol. Conserv. 125:467–474). In México, this gecko typically inhabits tropical and subtropical regions, usually associated with urban areas. Knowledge regarding ecological interactions between *H. frenatus* and other species in this region is poor (Álvarez-Romero et al. 2005. *In* Vertebrados Superiores Exóticos en México: Diversidad, Distribución y Efectos Potenciales, pp. 1–5. Instituto de Ecología, Universidad Nacional Autónoma de México. Bases de datos SNIB-CONABIO. Proyecto U020. México. D.F.). This report contributes to the knowledge of ecological interactions of this invasive species and also serves as the first report of predation on *H. frenatus* by *Q. mexicanus*, an opportunistic feeder that is known to prey on lizards (Gurrola-Hidalgo et al. 2009. Acta Zool. Mex. [n.s.] 25:427–430).

R. ISAAC ROJAS-GONZÁLEZ, Centro Regional de Investigación Pesquera en Lerma, Campeche INAPESCA-SAGARPA, Km 5 Carretera Campeche-Lerma, C.P. 24500 San Francisco de Campeche, Campeche, México (e-mail: ramon.rojas@inapesca.sagarpa.gob.mx); **ARMANDO T. WAKIDA-KUSUNOKI**, Centro Regional de Investigación Pesquera en Ciudad del Carmen, Campeche, México.

***HEMIDACTYLUS MABOUIA* (Tropical House Gecko). PREDATION.** This non-native lizard is broadly distributed throughout Brazil, occupying natural habitats despite commonly being associated with human settlements. Although relatively abundant in most regions, there is a considerable lack of information regarding its interactions with sympatric native species (Rocha and Anjos 2007. Braz. J. Biol. 67:485–491). Here we report predation on *Hemidactylus mabouia* (SVL = 133.9 mm) by a spider of the family Ctenidae (SVL = 20 mm).

At 1126 h on 20 October 2010, in the Museu de Biologia Mello Leitão, Santa Teresa municipality, Espírito Santo state, southeastern Brazil (19.5609°S, 40.3559°W; elev. 655 m), one of us (FAL) observed a ctenid spider on the wall of the Zoological Collection attached to and feeding on an adult of *H. mabouia*. The lizard was no longer alive. After minutes of observing the predation, FAL collected both specimens and transferred them to a small plastic container, where the spider remained attached to the lizards for two days.

Generally due to predation, non-native species have been considered the second most influential factor threatening biodiversity (McNeely et al. 2001. A Global Strategy on Invasive Alien Species. IUCN Gland. Switzerland and Cambridge UK. 50 pp.). This report adds to the literature that non-native species also play a role as prey for native species.

FIG. 1. Ctenid spider feeding on a *Hemidactylus mabouia*, in Santa Teresa, Espírito Santo, southeastern Brazil.

FABIANO A. LANSCHI, Museu de Biologia Mello Leitão, Av. José Ruschi, Nº 4, CEP 29.650-000, Santa Teresa, Espírito Santo, Brazil (e-mail: fabiano_lanschi@hotmail.com); **RODRIGO BARBOSA FERREIRA**, Department of Wildland Resources and Ecology Center, Utah State University, Logan, Utah 84322-5230, USA (e-mail: rodrigoecologia@yahoo.com.br).

***IGUANA DELICATISSIMA* (Lesser Antillean Iguana). ECTOPARASITISM.** *Iguana delicatissima* is a large, long-lived (up to 25 yrs) herbivorous generalist inhabiting less than 10 main islands in the Lesser Antilles from Anguilla to Martinique. *Iguana delicatissima* is primarily arboreal except on extreme xeric islands with limited tree diversity. Its historic range has been reduced dramatically because of habitat loss, non-native predators and competitors, hunting, road mortality, and genetic introgression with *I. iguana*. Consequently, *I. delicatissima* is listed as Endangered by the IUCN – the World Conservation Union (IUCN 2010. IUCN Red List of Threatened Species. Version 2010.4. <www.iucnredlist.org>. 13 June 2011).

Here we provide the first report of parasitism on *I. delicatissima* by the scale mite, *Hirstiella stamii* (Acariformes: Pterygosomatidae). To our knowledge, this is only the second ectoparasite (Kohls 1969. J. Med. Entomol. 6:439–442) reported for the species. From April to September 2009, and from April to June 2010, we captured and recorded body measurements from 906 subadult and adult *I. delicatissima* inhabiting the island of Dominica, West Indies. We also documented the presence of white, scale-like patches on the heads and dewlaps of 170 (18.8%) iguanas. Parasitized iguanas ranged in SVL from 16.3–36.3 cm (mean = 27.4, SD = 4.1), and body mass from 150–2050 g (mean = 928.3, SD = 347.5). Patches ranged in diameter from 2–10 mm and were located typically on the subocular, postocular, temporal, nasal, and/or canthal scales (Fig. 1). Patches also were located dorsally on the head in the region of the frontal, parietal, and/or interparietal scales. In five occurrences, patches were recorded on the dewlap. Voucher mite specimens are housed at the Museum of Biological Diversity, The Ohio State University with accession numbers OSAL0102567–70 (females), OSAL0102571 (male), and OSAL0102572–74 (larvae).

This is the first report of *I. delicatissima* parasitized by *H. stamii*. The mite was recorded previously from captive *I. iguana* at the Amsterdam Zoological Gardens in the Netherlands (Jack 1961. Ann. Mag. Nat. Hist. 13:305–314) and from non-native, wild-caught *I. iguana* in Florida, United States (Corn et al. 2011. J. Med. Entomol. 48:94–100).

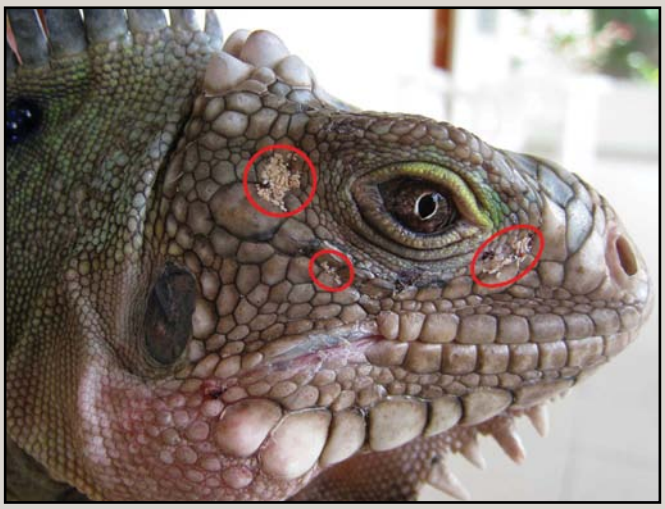

FIG. 1. Example of site attachment by the scale mite, *Hirstiella stamii*, on the head of *Iguana delicatissima* inhabiting the island of Dominica, West Indies. Patches circled in red.

We thank Arlington James and the staff at the Division of Forestry, Wildlife, and Parks for their support and permission to conduct this study. We thank our field assistants L. Prince, A. Mitchell, P. Meier, P. Shirk, and J. Reyes Velasco. These observations were made while conducting research through a San Diego Zoo Conservation Research Postdoctoral Fellowship.

DURDEN,** Department of Biology, Georgia Southern University, Statesboro, Georgia 30458, USA (e-mail: ldurden@georgiasouthern.edu); **HANS KLOMPEN**, Museum of Biological Diversity, The Ohio State University, 1315 Kinnear Road, Columbus, Ohio 43212, USA (e-mail: klompen.1@osu.edu).

***IGUANA IGUANA* (Green Iguana). PREDATION.** Double-toothed Kites (*Harpagus bidentatus*) are known to eat lizards, including juvenile *Iguana iguana* (Greene et al. 1978. J. Herpetol. 12:169–176). Double-Toothed Kites often forage by following monkeys (Egler 1991. Wilson Bull. 103:510–512; Fontaine 1980. Auk 97:94–98), capturing prey that the monkeys have flushed out of the brush by their movements. We did not find any reports of these kites taking prey directly from primates.

On 13 June 2011 at 1110 h, we captured two hatchling iguanas on the south edge of Bohio Reach, Panama Canal, Barro Colorado Natural Monument, Panamá (9.191111°N, 79.846111°W). Hatchlings were <0.25 m off the ground and 0.5 m apart in a patch of Canal Grass (*Saccharum spontaneum*) ca. 0.5 m from the water's edge. Each of us held one hatchling as we processed them in our boat (ca. 3 m from site of capture). During processing, we observed a Double-toothed Kite swoop from a tree ca. 4 m from us, appearing to watch our activity. The kite was initially perched ca. 6 m in a tree and swooped to a branch 2 m off the ground, loudly rustling the leaves. Upon attempting to release the first iguana (72 mm SVL, 11.4 g) onto a rock 3 m from the grass, it ran back into the lap of BAW. Thereafter, BAW walked the iguana to the grass to release it, during which time the kite flew toward his hand, hitting his hand with its wing, and directly snatching the iguana with its talons in a quick motion. The kite flew into nearby trees and out of sight with the iguana in its talons.

We thank California State University, Northridge (CSUN), the Smithsonian Tropical Research Institute (STRI), and the Society for Integrative and Comparative Biology for financial support and R. Espinoza for reviewing this note. Our research was conducted with permission from STRI and Autoridad Nacional del Ambiente and under IACUC protocols 0910-007b and 100316-0911-14 issued by CSUN and STRI, respectively.

BECK A. WEHRLE (e-mail: beck.wehrle.367@my.csun.edu) and **JORGE A. GUZMAN,** California State University, Northridge, Department of Biology, Northridge, California 91330, USA.

***LANKASCINCUS FALLAX* (Peters' Litter Skink). REPRODUCTION.** *Lankascincus fallax* is a subfossorial skink endemic to Sri Lanka (Somaweera and Somaweera 2009. Lizards of Sri Lanka, A Colour Guide with Field Keys. Edition Chimaira, Frankfurt am Main. 303 pp.). The purpose of this note is to present information on the reproductive biology of *L. fallax*.

Thirty-one *L. fallax* (15 males, mean SVL = 39.3 mm ± 2.2 SD, range = 36–45 mm; 16 females, mean SVL = 39.1 mm ± 2.4 SD,

range = 35–43 mm) were examined from the following localities: Central Province (7.2631°N, 80.6028°E), CCA (= Christopher C. Austin, field number) 1745, 2361, 2362, 2368, 2383, 2407–2411, 2413, 2416–2418, 2422–2424, 2448, 2453; North Central Province (8.3500°N, 80.3833°E), CCA 2375–2377, 2386, 2387, 2391, 2392; North Western Province (7.7500°N, 80.1667°E), CCA 2425, 2426; Sabaragamuwa Province (6.7500°N, 80.5000°E), CCA 2445; Southern Province (7.9500°N, 80.7500°E), CCA 2452; Western Province (7.1807°N, 79.8841°E), CCA 2359. *Lankascincus fallax* were collected in August 1999 and November 2002 and were deposited in the herpetology collection of the National Museum of Sri Lanka, Colombo, Sri Lanka.

For histological examination, the left gonad was removed to check for yolk deposition in females and spermiogenesis (sperm formation) in males. Counts were made of enlarged ovarian follicles (3 mm diameter) or oviductal eggs. Tissues were embedded in paraffin, sectioned at 5 µm using a rotary microtome and stained with hematoxylin followed by eosin counterstain.

All males of *L. fallax* were from November and were undergoing spermiogenesis. The smallest spermiogenic male measured 36 mm SVL (CCA 2413). Fifteen females of *L. fallax* were from November, one was from August. All were reproductively active, with 13 containing oviductal eggs and two containing enlarged follicles (> 4 mm). Mean clutch size for fifteen females was 1.8 ± 0.44, range: 1–2. Three females with two oviductal eggs, each (CCA 2383, 2387, 2391) were undergoing concomitant yolk deposition for a subsequent clutch indicating *L. fallax* produces multiple clutches annually. The smallest reproductively active female *L. fallax* measured 35 mm SVL (two oviductal eggs, CCA 2453).

We thank the Department of Wildlife Conservation, Sri Lanka for permit WL/3/2/14/12, to collect *L. fallax*. This research was funded in part by the People's Trust for Endangered Species to ID and a National Foundation Science grant DEB 044513 to CCA.

***LEPIDODACTYLUS LUGUBRIS* (Mourning Gecko). FORAGING MOVEMENT.** *Lepidodactylus lugubris* is a small (45 mm) gecko native to Indo-Australia. The species has been widely introduced in tropical areas throughout the world, including the Bocas del Toro islands of the Republic of Panama. This species is predominantly a nocturnal insectivore. However, individuals are known to supplement their diet with nectar and ripe fruit, and have been observed to forego insects when feeding on nectar (Perry and Ritter 1999. Herpetol. Rev. 30:166–167). They have also been documented to change their typical behavior to gain access to sugar sources (McCoid and Hensley 1993. Herpetol. Rev. 22:8–9). Thus, sugar and nectar may serve as a behaviorally influential dietary resource for this species.

A small population of *L. lugubris* located on Isla Coln at the Bocas Del Toro Biological Station in the Republic of Panama was noted to undergo mass concerted movements at dusk from their daytime retreat within a building to a nearby *Morinda citrifolia* tree. Within the tree, individuals were observed consuming excretions from the pores of the fruit, as well as nectar from the flowers. After initial observation, I removed all vegetation in contact with the building that was originating from, or in the vicinity of, the *M. citrifolia* tree. In place of the vegetation, I constructed a series of four rope bridges (diameter: 3.2 mm) that served to ensure access to the tree was limited to crossing the rope bridge. One rope bridge connected a building beam to the shortened *M. citrifolia* branch at their previous point of tree entry. The other three bridges were connected to nearby vegetation lacking fruit or flowers to ensure movement was non-random. The same building beam was connected to a mango tree (*Mangifera indica*) and to two independent, unidentified woody shrubs. After the first two nights it became apparent that geckos were only using the bridge connected to *M. citrifolia*, so additional bridges were not monitored on subsequent nights. Due to the diameter of the rope, individuals were only able to cross single-file, simplifying quantification. I recorded their movements across the *M. citrifolia* rope bridge at dusk for six days from the period of 30 June to 7 July 2005 (1830–2030 h) and from 0530–0630 h on 8 July 2005. Crossing individuals were marked on their back with a water-based, non-toxic permanent paint marker, similar to DECOCOLOR® paint markers. The number of marked and unmarked individuals was recorded each night.

The majority of movement occurred during or immediately after dusk. Movements after that period were less frequent and greatly interspersed. Over a standardized period of two hours following dusk, a mean of 39 (range: 35–54) geckos were observed to cross to the *M. citrifolia* each night. With the exception of the first night when all individuals were new to the altered pathway, approximately half of the individuals recorded crossing each night were unmarked. This suggests that individuals readily adapt behavior to gain access to foraging resources, and do not forage in the tree every night. On the morning of 8 July 2005, 69 individuals returned. I also observed marked individuals up to 12.49 m straight line distance from the crossing point, feeding under building lights in concert with *Hemidactylus frenatus* (House Gecko; native to southeastern Asia, widely introduced elsewhere). No *H. frenatus* individuals were observed to cross into the *M. citrifolia* tree.

The distance I observed marked individuals from the *M. citrifolia* crossing point suggests geckos were willing to move over a considerable distance of open space to gain access to nectar, and that nectar is an important food source for this population. Petren and Case (1998. Proc. Natl. Acad. Sci. 95:11739–11744) found that increasing topographic complexity of foraging areas drastically reduced competition between *L. lugubris* and *H. frenatus*. The presence of *H. frenatus* at the structurally simple insect feeding stations used by *L. lugubris* and their absence at the structurally complex *M. citrifolia* may indicate the observed phenomenon is one strategy used by *L. lugubris* to reduce interspecific competitive interactions.

I am grateful to Dr. Tom Jones and the owners of the Bocas Del Toro Biological Station restaurant for their contributions to this study.

MELIA G. NAFUS, Department of Wildlife, Fish, and Conservation Biology, University of California, Davis, California 95616, USA; e-mail: mgnafus@ucdavis.edu.

***LIOLAEMUS ESPINOZAI*. PREDATION.** *Liolaemus espinozai* has only been recently described and little is known about its natural history. It is found southeast of the Nevados del Aconquija in Catamarca province, Argentina, 2200–2800 m elev. (Abdala 2005.

FIG. 1. *Philodryas psammophidea* seizing a *Liolaemus espinozai* just below the neck.

Rev. Esp. Herpetol. 19:5–17). It is a medium-sized lizard (approx. 60 mm SVL). The colubrid *Philodryas psammophidea* occurs within the distribution of *L. espinozai* and is known to feed on lizards (Scrocchi et al. 2006. Serpientes del Noroeste Argentino. Miscelanea, Fundación Miguel Lillo. 174 pp.). Here we report on an occurrence of predation by this snake on *L. espinozai.*

On 18 February 2005, at ca. 1700 h, in Campo el Arenal, Catamarca (27.21°S, 66.23°W, datum WGS84; 2858 m elev.), an adult female *L. espinozai* was seen moving towards a shrub, perhaps responding to the presence of the observers. A *Philodryas psammophidea* happened to be in the aforementioned shrub. It immediately attacked the lizard, grasping it by the side of the body (Fig. 1). The lizard bit the snake on the side of its neck, a defensive response that might sometimes be effective as an antipredator mechanism (e.g., Leal and Rodríguez-Robles 1995. Copeia 1995:155–161). The snake slightly constricted the lizard, a technique many colubrids use to overcome larger prey (Zug 1993. Herpetology: An Introductory Biology of Amphibians and Reptiles. Academic Press, San Diego, California. 527 pp.). Later the snake located the lizard's head and ingested it headfirst.

We thank CONICET, CIUNT G430, Fundación Miguel Lillo, Tucumán, and Instituto de Ambientes de Montaña y de Regiones Áridas, Universidad Nacional de Chilecito, La Rioja, Argentina for financial support.

Áridas, Universidad Nacional de Chilecito, Ruta los peregrinos s/nº, La Rioja, Argentina (e-mail: gabrielagall@gmail.com); **MONIQUE HALLOY,** Instituto de Herpetología, Fundación Miguel Lillo, Miguel Lillo 251, Tucumán, Argentina (e-mail: mhalloy@webmail.unt.edu.ar); **CRISTIAN ABDALA**, CONICET (e-mail: samiryjazmin@gmail.com).

***MESALINA GUTTULATA* (Desert Lacerta). ENDOPARASITES.** *Mesalina guttulata* occurs in North Africa from Western Sahara to Egypt, Sinai, Israel, Jordan, Syria, Iraq, Saudi Arabia, W Yemen, Niger, and Eritrea (Sindaco and Jeremcenko 2008. The Reptiles of the Western Palearctic. Monografie della Societas Herpetologica Italica – I, Latina, Italy. 579 pp.). To our knowledge there are no records of helminths from *M. guttulata* and this note's purpose is to establish the initial helminth list for *M. guttulata.*

A sample of 78 *M. guttulata* (mean SVL = 42.9 mm ± 5.2 SD, range = 30–54 mm) collected 1949 to 2007 from Israel was borrowed from the Natural History Collections, Tel-Aviv University, (TAUM) Tel-Aviv, Israel for coelomic helminth examination. The body cavity was opened and examined for helminths. Four *M. guttulata* (TAUM 2979, 4004, 8468, 13172) collected in the Southern District, Israel, contained macroscopically visible, oblong, whitish bodies, of ca. 1 mm in length. They were regressively stained in hematoxylin, cleared in xylol, mounted in balsam on a glass slide, coverslipped, examined under a compound microscope and identified as larval cestodes, tetrathyridea of *Mesocestoides* sp. Prevalence (number infected/number examined × 100) was 5.1%. Mean intensity (mean number helminths per infected lizard ± 1 SD) was 32.8 ± 19.1 SD, range = 10–56. Vouchers were deposited in the United States National Parasite Museum (USNPC), Beltsville, Maryland as USNPC (104866, 104867).

Mesocestoides is a cosmopolitan genus with a unique larval form, the tetrathyridium; reptiles are common intermediate hosts in what is thought to be a three-host life cycle (Padgett and Boyce 2005. J. Helminthol. 79:67–73). A list of amphibian and reptile hosts for *Mesocestoides* spp. is in Goldberg et al. (2004. Comp. Parasitol. 71:49–60). *Mesalina guttulata* represents a new host record for tetrathyridea of *Mesocestoides* sp.

We thank Shai Meiri (TAUM*)* for permission to examine *M. guttulata* and Erez Maza (TAUM) for processing the loan.

***PHELSUMA GRANDIS* (Madagascar Day Gecko). PREY.** *Phelsuma grandis* is native to northern Madagascar (Henkel and Schmidt 2000. Amphibians and Reptiles of Madagascar and the Mascarene, Seychelles, and the Comoro Islands. Krieger Publ. Co., Malabar, Florida. 319 pp.), and has been introduced to at least nine islands in the Florida Keys (Krysko and Hooper 2007. Gekko 5:33–38; Krysko and Sheehy 2005. Carib. J. Sci.

FIG. 1. Nonindigenous *Phelsuma grandis* preying upon a nonindigenous Bark Anole (*Anolis distichus*) on Ramrod Key, Monroe County, Florida.

41:169–172). *Phelsuma grandis* is known to consume mostly nectar, pollen, and arthropods (Demeter 1976. Internat. Zoo Yearbk. 16:130–133; Krysko and Hooper, *op. cit.*; Tytle 1992. Vivarium 2:15–19), but has also been documented consuming lizards such as neonate *P. grandis* (Krysko et al. 2003. Florida Sci. 66:222–225). In this note, we report *P. grandis* preying upon a nonindigenous Bark Anole (*Anolis distichus*) in Florida.

On 5 July 2011 at 1930 h, we observed an adult female *Phelsuma grandis* near the junction of West Indies Drive and Cayman Lane, Ramrod Key, Monroe Co., Florida, USA (24.65154°N, 81.40447°W, WGS84; elev. <1 m). This gecko was about 1.8 m above ground on a nonindigenous Umbrella Tree (*Schefflera actinophylla*) and had an adult female *Anolis distichus* in its mouth. We quickly took photographs with an 8 MP camera phone (Florida Museum of Natural History, photographic voucher UF 165521; Fig. 1), but after returning about 3 min later with other photographic equipment both lizards were gone. This is the first known record of this nonindigenous gecko preying upon a nonindigenous anole in Florida.

SMITH** (e-mail: hellcat@ufl.edu), Division of Herpetology, Florida Museum of Natural History, Dickinson Hall, University of Florida, Gainesville, Florida 32611, USA; **ANDREW P. BORGIA**, P.O. Box 4346, Key West, Florida 33041, USA.

***PHOLIDOBOLUS MONTIUM* (Lagartija Minadora). PREDATION.** *Pholidobolus montium* is a gymnopthalmid lizard known from interandean basins and valleys in northern and central Ecuador (Provincias Imbabura, Pichincha, Cotopaxi) and southern Colombia at elevations between 2000–3190 m (Montanucci 1973. Misc. Publ. Univ. Kansas Mus. Nat. Hist. 59:1–52; Reeder 1996. Herpetologica 52:282–289). Here we provide the first report on natural predators of this species.

On 10 April 2009, FAV collected a subadult female *Liophis epinephelus albiventris* (SVL = 221.0 mm, TL = 64.0 mm; QCAZ 8044) in Ecuador, Pichincha Province, Tababela (0.11362°S, 78.36331°W, 2374 m elev.), which had recently eaten. A few minutes after capture, the snake regurgitated two prey items: a full specimen of *Pholidobolus montium* (SVL = 47.5 mm; QCAZ 10064) and a hindlimb of the marsupial frog *Gastrotheca riobambae*. On 16 May 2009 at 1100 h in Tababela (0.0986395°S, 78.36936°W, 2346 m elev.), FAV observed a predation event in which a juvenile male specimen of the snake *Mastigodryas pulchriceps* (SVL = 218.0 mm, TL = 80.0 mm; QCAZ 8045) was found ingesting a specimen of *P. montium* (QCAZ 8046, SVL = mm). First, the snake grasped the lizard with its mouth (Fig. 1). Then the snake ingested the lizard starting at the posterior region of the body. The same predatory behavior has been reported for *Mastigodryas melanolomus* (Dehling 2009. Herpetol. Rev. 40:357). This is the first record of predation of *Pholidobolus montium* by *L. e. albiventris* and *M. pulchriceps*. The snakes and the lizards are deposited in the herpetological Collection of Museo de Zoología QCAZ, Pontificia Universidad Católica del Ecuador.

FIG. 1. Predation of *Pholidobolus montium* by *Mastigodryas pulchriceps*.

***PHRYNOSOMA MODESTUM* (Round-tailed Horned Lizard). PREDATION.** *Phrynosoma modestum* occurs from extreme southeastern Colorado and western Oklahoma to western Texas, southern New Mexico (USA), and then south through Chihuahua, Coahuila, Zacatecas, and San Luis Potosi (Mexico) (Espinal and Smith 2007. Amphibians and Reptiles of the State of Coahuila, Mexico. Universidad Nacional Autónoma de México and Comisión Nacional Para El Conocimiento y Uso de la Biodiversidad. 550 pp.; Hodges 2009. *In* Jones and Lovich [eds.], Lizards of the American Southwest, pp. 186–189. Rio Nuevo Publ., Tucson, Arizona; Sherbrooke 2003. Introduction to the Horned Lizards of North America. University of California Press, Berkeley, California. 178 pp.). Tarantulas of the genus *Aphonopelma* (consisting of approximately 87 species that inhabit North America) are documented predators. Along with other genera of the subfamily Theraphosinae, the majority of the species are found in North America. Fifty-one species have been reported for the United States and 24 or 25 for Mexico (Smith 1995. Tarantula Spiders: Tarantulas of the U.S.A. and Mexico. Fitzgerald Publ., London. 196 pp.). Predation on *P. modestum* has been documented by Sherbrooke (2003, *op. cit.*; 2010 Herpetol. Rev. 41:356) and Hodges (2009, *op. cit.*), who mention that the species is predated by collared lizards (*Crotaphytus* spp.), Greater Roadrunners (*Geococcyx californianus*), Loggerhead Shrikes (*Lanius ludovicianus*), and grasshopper mice (*Onychomys* spp.).

While conducting a survey on 22 July 2011 on the araneofauna of the Bolson of Cuatro Cienegas Region, Coahuila, Mexico,

FIG. 1. A female *Aphonopelma* sp. preying on a female *Phrynosoma modestum*, in the valley of Cuatro Cienegas, Coahuila, Mexico.

near El Mezquite (26.92268°N, 102.43409°W, datum NAD27; 1030 m elev.), we came across a female *Aphonopelma* sp. (55.20 mm TL, 19.64 mm median length of the carapace) at 1745 h that had immobilized a female *Phrynosoma modestum* (SVL = 84.44 mm; TL = 154.53 mm). As we approached the tarantula, after taking a series of photos, it released the horned lizard. Inspecting the lizard carefully, we found no sign of puncture holes on the head or any other part of the body, but it appeared that a great quantity of blood had come from the left eye. After measuring the lizard we released it *in situ*, and it appeared to move with some difficulty, perhaps from the trauma of the event. The tarantula was collected for future behavioral studies (CAFCB-UANL-T500). At present the species has not been identified. This event occurred about 40 cm from a burrow (ca. 11.5 cm diam), which it may have occupied.

(e-mail: rodolfoarm85@yahoo.com); **CARLOS SOLIS-ROJAS,** Universidad Autónoma de Nuevo León, Facultad de Ciencias Biológicas, Laboratorio de Entomología y Artrópodos, Colección Aracnológica, Apartado Postal 105-F, San Nicolás de los Garza, Nuevo León, C.P. 66450, México, (e-mail: csolis01@hotmail.com).

***PLESTIODON FASCIATUS* (Five-lined Skink). HIBERNATION.** Few published observations of hibernation or hibernacula are available for *Plestiodon fasciatus* (COSEWIC 2007. COSEWIC Assessment and Update Status Report on the Five-lined Skink *Eumeces fasciatus* (Carolinian Population and Great Lakes/St. Lawrence Population) in Canada. Committee on the Status of Endangered Wildlife in Canada. Ottawa. vii + 50 pp. [www.sararegistry.gc.ca/status/status_e.cfm]). At ca. 1000 h on 7 March 2011 at Point Pelee National Park (41.93148°N, 82.51252°W; WGS 84) in Essex County, Ontario, Canada, a skink was unearthed by a backhoe 34 m ESE of the Visitor Centre in an open area of deciduous forest during an archaeological inspection before septic tank installation. The field crew present (G. Almasi, D. Dawdy, J. Goundry, M. Teal, D. Kipping, S. Hossain, and A. Miller) notified park resources staff. The lone adult male *P. fasciatus* (70 mm SVL, 150 mm TL) was found ca. 23 cm deep in loamy sand soil that was under ca. 10 cm of snow. Ground frost penetration was ca. 8–10 cm in the vicinity but soil appeared unfrozen at the spot where the skink was observed. No stumps, logs, or large roots were present but a cedar stump was about 2.4 m from the skink. There was no sign of obvious tunneling by the skink. Ambient conditions were sunny (temp: -5°C; wind: NE 7 km/h; RH: 79%). The specimen appeared in good condition but was torpid upon capture. Slight movements and partial eyelid opening occurred during handling and photographing the specimen and it remained lethargic for the first two days of holding indoors. The specimen became fully active after about 5 days and was maintained on a cricket diet until being released on 28 April in healthy condition after annual skink activity resumed. Skink hibernacula have not been observed in the park but in several previous years we observed single or small numbers of individuals on the first day of annual activity adjacent to skink-sized holes under woody debris in sandy soils within their home ranges. Similar observations were reported from Kansas (Fitch 1954. Univ. Kansas Publ. Mus. Nat. Hist. 8:1–156). Skinks have also entered the Visitor Centre building during previous winters. Some literature has noted Five-lined Skinks hibernating alone, in pairs, or with small groups of other lizards, in or under logs, stumps, sawdust or debris piles, ground litter, mammal burrows, building foundations, under rocks, or within rock crevices (Conant 1951. Am. Midl. Nat. 20:1–200; Fitch 1954, *op. cit.*; Hamilton 1948. Copeia 1948:211; Harding 1997. Amphibians and Reptiles of the Great Lakes Region. Univ. Michigan Press, p. 231; Linsdale 1927. Copeia 1927:75–81; Neill 1948. Herpetologica 4:107–114) but few details have been published. Tihen (1937. Trans. Kansas Acad. Sci. 40:401–409) reported two *P. fasciatus* hibernating 2.5 m underground in Kansas. Point Pelee is a natural sandspit in Lake Erie so skinks must overwinter below the frost line but above the shallow and fluctuating water table where late winter–early spring flood mortality has occurred in communal snake hibernacula (T. Linke, unpubl. park records). Our note adds to the existing literature and provides the first report of overwintering conditions for the endangered Carolinian population of *P. fasciatus* in southwestern Ontario and for the northern portion of its range.

HECNAR, Department of Biology, Lakehead University, Thunder Bay, Ontario P7B 5E1, Canada (e-mail: shecnar@lakeheadu.ca); **TAMMY DOBBIE** (e-mail: tammy.dobbie@pc.gc.ca), **KEVIN LECLAIR** (e-mail: kevin.leclair@pc.gc.ca), and **RACHEL THORNDYKE** (e-mail: rachel.thorndyke@pc.gc.ca), Parks Canada Agency, Point Pelee National Park, Leamington, Ontario N8H 3V4, Canada.

***PLESTIODON FASCIATUS* (Common Five-lined Skink). BIFURCATION.** *Plestiodon fasciatus* is the only lizard species in Michigan known to occur outside of Tuscola County, and is relatively abundant throughout the Lower Peninsula (Harding 1997. Amphibians and Reptiles of the Great Lakes Region. University of Michigan Press, Ann Arbor. 378 pp.). On 11 July 2011 at 1000 h we observed an adult with a bifurcated (bifid) tail under a pine log in Northern Midland County (43.68073°N, 84.29604°W). The tail was bifurcated somewhat vertically at the posterior end, and appeared to have been lost and regrown at least once prior to the splitting event. The dorsal fork was longer than the ventral fork. A non-lethal tissue sample with accession number FTB2749 was collected under a permit to ADM from the Michigan Department of Natural Resources and Environment and deposited in the Burbrink genetic resources collection at College of Staten Island, Staten Island, New York.

ALEXANDER D. McKELVY, CUNY Graduate Center and Biology Department, College of Staten Island, Staten Island, New York 10314, USA (e-mail: amckelvy@gc.cuny.edu); **CHRIS STARK,** Midland, Michigan.

***PLESTIODON LATICEPS* (Broad-headed Skink). HERBIVORY.** *Plestiodon laticeps* is a common and widespread North American skink that, like most members of its genus, is generally regarded as a strict carnivore (Mount 1975. The Reptiles and Amphibians of Alabama. Auburn Univ. Agric. Exp. Sta., Auburn, Alabama. 347 pp.; Jensen et al. [eds.] 2008. Amphibians and Reptiles of Georgia. Univ. Georgia Press, Athens. 575 pp.). At 1400 h on 29 May 2011, I observed herbivory by a free-ranging adult male in a partially wooded section of my backyard, which is situated in a large-lot residential subdivision that supports a substantial skink population in Tallahassee, Leon Co., Florida, USA (30.48341°N, 84.18301°W; datum NAD83; elev. 40 m). Observations were made in light shade at an air temperature of 32°C. Five minutes after leaving a ripe strawberry and canned dog food in front of a

captive adult female Florida Box Turtle (*Terrapene bauri*: Butler et al. 2011. Biol. J. Linn. Soc. 102:889–901), I returned to see the skink grasping the strawberry, which was at least as large as his head, directly beneath the turtle's mouth. Upon observing me, he carried the berry 1 m to feed on it beneath an azalea bush on the opposite side of a chain link fence, where I observed him for 15 minutes. During feeding, he repeatedly jerked his head and upper body to remove bites of strawberry, which he swallowed. No animal life was present on the berry. When I moved to within 1 m, the skink carried the remaining berry 75 cm to another spot, where he finished swallowing it, including the top rosette of greenery.

Although many other skinks regularly include some plant food in their diets (Cooper and Vitt 2002. J. Zool., Lond. 257:487–517; Sazima et al. 2005. Biota Neotrop. 5:185–192), this may be only the second report of herbivory in the monophyletic clade of East Asian and North American skinks recognized as *Plestiodon* by Brandley et al. (2005. Syst. Biol. 54:373–390). Cooper and Vitt (*op. cit.*) mentioned that *P. laticeps* sometimes eats grapes and berries in the field but offered no supporting data. These observations are perhaps not surprising given the association of large body size with herbivory and omnivory in lizards (Cooper and Vitt, *ibid.*). *P. laticeps* is among the largest members of its clade. Thus, plant matter potentially may form a larger portion of its diet than traditionally realized. Whether it responds to plant chemicals, a trait generally typical of herbivorous but not insectivorous lizards (Cooper et al. 2000. J. Chem. Ecol. 26:1623–1634), would be especially noteworthy.

I am indebted to John Iverson for facilitating a literature review of lizard herbivory.

DALE R. JACKSON, Florida Natural Areas Inventory, Florida State University, 1018 Thomasville Road, Suite 200-C, Tallahassee, Florida 32308, USA (e-mail: djackson@fnai.org).

***PODARCIS HISPANICA* (Iberian Wall Lizard). CAUDOPHAGY.** On 23 February 2011 at 1320 h, while conducting field sampling in a rocky area close to Nava de Francia (Salamanca, Spain), we observed a male *Podarcis hispanica* eating the tail from a conspecific. We immediately started to video record this behavior for the next 1 min. and 32 sec. The video shows that the tail was extending about 17 mm out of the mouth of the lizard, and that the individual was trying to swallow it by rubbing the tail against the surface of a granite rock. The lizard moved forward ca. 40 cm and performed repeated movements during the whole process, probably to help in swallowing the tail: 1) The lizard rubbed the left side of the head against the rock 17 times and the right side four times. Of the left-side movements, 13 of them had an associated head rotation that made them more abrupt and vigorous; 2) the lizard made what appeared to be swallowing motions (raising the snout and pulling the head back) 23 times; 3) the lizard moved the head up and down on 7 occasions and side-to-side for at least 3 times (see Hews and Dickhaut 1989. Herpetol. Rev. 20:71 for a description of a similar movement); 4) the lizard opened and closed the mouth at least 12 times. The individual continued to bask in open sun, alternating between the described behaviors and returning to its basking position five separate times. The lizard kept its snout in contact with the rock for at least 45 sec., rubbing it on the substrate, and even might have used its right forelimb at least twice to facilitate ingestion of the tail.

We captured the lizard (47 mm SVL; 2 g) at 1342 h and it had swallowed almost the entire tail, with only 7 mm protruding from the mouth, compared with more than 17 mm protrusion detected at the beginning of the process. The lizard had a non-regenerated tail that was 92 mm long. The tail consumed was 48 mm long, likely from an adult. The lizard was released to the field immediately after measurement.

The contents of several stomachs from mainland *Podarcis hispanica* have been analyzed (Pérez-Mellado 1983. Studia Oecologica 4:89–114; Pérez-Mellado 1998. Fauna Ibérica 10:258–272) and conspecific remains were absent. Hence, this is the first record of conspecific caudophagy by *Podarcis hispanica*.

We thank the Consejería de Medio Ambiente of Junta de Castilla y León for issuing a permit of scientific capture (permit number: EP/CYL/472/2010), with research funded by the project: CGL2009-12926-C02-02 from the Spanish Ministry of Science and Innovation. The first author (ZOD) was benefited by a predoctoral grant of the University of Salamanca. For those interested, the video recording may be obtained by contacting the lead author.

ZAIDA ORTEGA DIAGO (e-mail: zaidaortega@usal.es) and **VALENTÍN PÉREZ-MELLADO,** Universidad de Salamanca, Departamento de Biología Animal, Campus Miguel de Unamuno s/n, Salamanca, 37007, Spain.

***QUEDENFELDTIA TRACHYBLEPHARUS* (Atlas Day Gecko). ENDOPARASITES.** *Quedenfeldtia trachyblepharus* is known from the Atlas Mountains of Morocco where it inhabits rock faces and boulders from 0–4000 m (Schleich et al. 1996. Amphibians and Reptiles of North Africa. Koeltz Sci. Publ., Koenigstein, Germany. 630 pp.). To our knowledge there are no helminths known from *Q. trachyblepharus*. The purpose of this note is to establish the initial helminth list for *Q. trachyblepharus*.

A sample of 69 *Q. trachyblepharis* (mean SVL = 38.7 mm ± 3.5 SD, range = 31–46 mm) collected in May 1974 at Igrherm, Taroudant Province, Souss-Massa Draa Region, Morocco (30.06250°N, 8.40833°W, datum WGS 84; elev 1600–1700 m) was borrowed from the herpetology collection of the Field Museum of Natural History (FMNH) for coelomic helminth examination. The body cavity was opened and examined for helminths. Two *Q. trachyblepharus* (FMNH 197642, 197718) contained 22 and 49 macroscopically visible, oblong, whitish bodies ca. 1 mm in length. One (FMNH 197652) contained fragments of a cestode protruding from the broken small intestine. Helminths were regressively stained in hematoxylin, cleared in xylol, mounted on a glass slide, coverslipped, examined under a compound microscope and identified as larval cestodes, tetrathyridea of *Mesocestoides* sp. (FMNH 197642, 197718). Prevalence (number infected/number examined ×100) was 3.0%. Mean intensity (mean number helminths per infected lizard ± 1 SD) was 35.5 ± 19.1). Found in FMNH 197652 were proglottids of an adult cestode consistent with *Oochoristica*. Voucher helminth specimens were deposited in FMNH.

Mesocestoides is a cosmopolitan genus with a unique larval form, the tetrathyridium; reptiles are common intermediate hosts in what is thought to be a three-host life cycle (Padgett and Boyce 2005. J. Helminthol. 79:67–73). A list of amphibian and reptile hosts for *Mesocestoides* spp. is in Goldberg et al. (2004. Comp. Parasitol. 71:49–60). Regarding the *Oochoristica* sp., the scolex was not present so species identification was not possible but ovary morphology was most similar to *O. chabaudi* described from *Chalcides mionecton* from Morocco by Dolfuss (1954. Arch. Inst. Pasteur Maroc. 4:654–714.). *Quedenfeldtia trachyblepharus* represents a new host record for *Mesocestoides* sp. and has not been previously reported for a species of *Oochoristica*.

We thank Alan Resetar (FMNH) for permission to examine *Q. trachyblepharis*.

STEPHEN R. GOLDBERG, Department of Biology, Whittier College, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu); **CHARLES R. BURSEY,** Department of Biology, Pennsylvania State University, Shenango Campus, Sharon, Pennsylvania 16146, USA (e-mail: cxb13@psu.edu).

***SCELOPORUS MARMORATUS* (Northern Rose-bellied Lizard). KYPHOSIS AND SCOLIOSIS.** Kyphosis and scoliosis is occasionally seen in green iguanas and other lizards and these malformations can result from genetic defects, malnutrition or improper environmental conditions during incubation, primarily by temperature levels that are too high or too low for some or all of the incubation clutch (Mader 1996. Reptile Medicine and Surgery. W.B. Saunders Co., Philadelphia, Pennsylvania. 512 pp.). A case with both kyphosis and scoliosis in sceloporine lizards has been recently reported (Mitchell and Georgel 2005. Herpetol. Rev. 36:183–184).

On 15 September 2010, we collected a female *Sceloporus marmoratus* (SVL = 28 mm SVL; tail length = 39 mm; 0.91 g) active on soil litter in submontano scrubland in the federal natural protected area Cerro de La Silla in the municipality of Juarez, Nuevo Leon, Mexico (25.589861°N, 100.168306°W, datum WGS84; 531 m elev.). The lizard exhibited two vertical curvatures of the spine (kyphosis), one behind the head in the pectoral region and one over the pelvic girdle. In addition, the detached tail had four, alternating lateral curves (scoliosis). Apparently, these malformations do not appear to decrease the probability of survival of lizards (Frutos et al. 2006. Herpetol Rev. 37:468–469; Mitchell and Georgel, *op. cit.*; Norval et al. 2010. Herpetol. Rev. 41:224–225). The lizard was deposited in the herpetological collection of the Universidad Autónoma de Nuevo León, Facultad de Ciencias Biológicas (UANL 7250). To our knowledge, this is the first reported occurrence of these conditions in *S. marmoratus* in the wild.

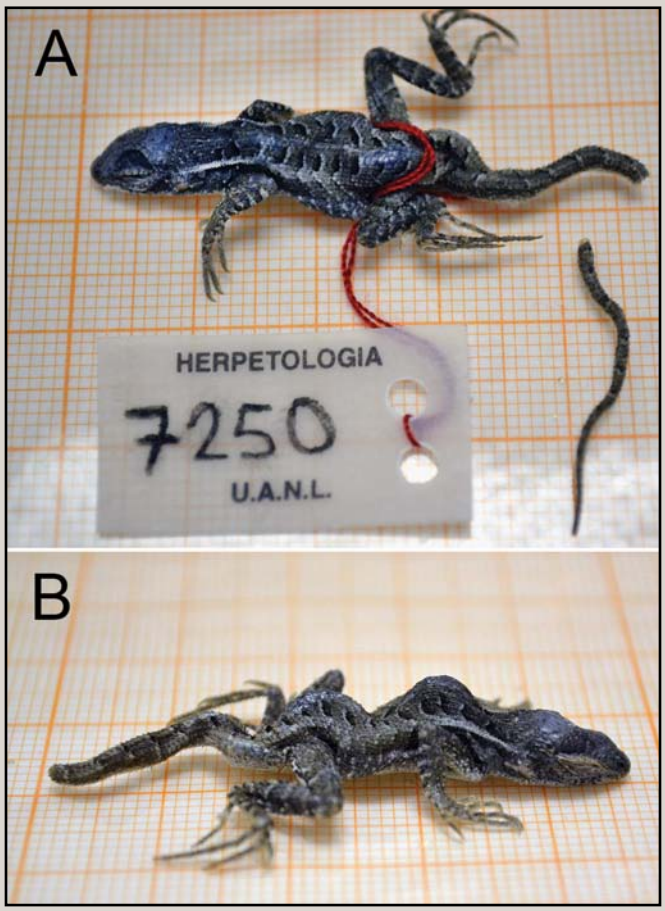

FIG. 1. Juvenile female *Sceloporus marmoratus* illustrating multiple kyphosis and scoliosis. A) Dorsal view with detached tail. B) Lateral view.

JERÓNIMO A. CHÁVEZ-CISNEROS (e-mail: jeroachavezc@gmail.com) and **DAVID LAZCANO**, Universidad Autónoma de Nuevo León, Facultad de Ciencias Biológicas, Laboratorio de Herpetología, Apartado Postal-513, San Nicolás de los Garza, Nuevo León, CP. 66450, México.

***SCELOPORUS SMARAGDINUS* (Bocourt's Emerald Lizard), *SCELOPORUS TAENIOCNEMIS* (Guatemalan Spiny Lizard). ENDOPARASITES.** Both *Sceloporus smaragdinus* and *S. taeniocnemis* occur in southeastern Mexico (Chiapas) and Guatemala in pine and cloud forests; *S. smaragdinus* at 2000–4000 m elev.; *S. taeniocnemis* at 1200–2500 m elev. (Köhler 2003. Reptiles of Central America. Herpeton, Offenbach, Germany. 367 pp.). The purpose of this note is to establish the initial helminth lists for *S. smaragdinus* and *S. taeniocnemis*.

Specimens of the two species collected in Guatemala were borrowed from the herpetology collection of the Natural History Museum of Los Angeles County (LACM), California, USA, and examined for helminths: one male *Sceloporus smaragdinus* (LACM 39871; SVL = 61.0 mm; Huehuetenango Department, Chemal, April 1968; 15.5500°N, 91.5000°W WGS 84, 3288 m elev.); and three *S. taeniocnemis* (LACM 40285–40287; 2 females, 1 male, mean SVL = 73.7 mm ± 4.2 SD; range = 69–77 mm; Huehuetenango Department, Barillas, April 1968; 15.8036°N, 91.3158°W WGS 84, 1554 m elev.).

The digestive tract was removed and opened. One species of Nematoda was found in the large intestines of all specimens, cleared in a drop of glycerol on a microscope slide, coverslipped, studied under a compound microscope, and identified as *Spauligodon oxkutzcabiensis*. In *S. taeniocnemis*, prevalence (number infected lizards/lizard sample × 100) was 100% (3/3); mean intensity of infection (mean number of helminths per infected lizard ± SD) was 9.3 ± 10.2 SD, range = 2–21. For *S. smaragdinus*; prevalence was 100% (1/1). Selected specimens of *Spauligodon oxkutzcabiensis* were deposited in the United States National Parasite Collection, Beltsville, Maryland, USA as *Sceloporus smaragdinus*: USNPC 104832; *S. taeniocnemis*: USNPC 104833.

Spauligodon oxkutzcabiensis, an oxyurid nematode, does not utilize an intermediate host (Anderson 2000. Nematode Parasites of Vertebrates: their Development and Transmission. CABI Publishing, Oxon, U.K. 650 pp.). Infection likely occurs when lizards ingest eggs from infected soil while feeding. *Spauligodon oxkutzcabiensis* is a common parasite in lizards from Mexico, Central America (Bursey et al. 2007. Comp. Parasitol. 74:108–140), and South America (Goldberg and Bursey 2010. Comp. Parasitol. 77:91–93). *Sceloporus smaragdinus* and *S. taeniocnemis* represent new host records for *Spauligodon oxkutzcabiensis*. Guatemala is a new locality record.

We thank Christine Thacker (LACM) for permission to examine *S. smaragdinus* and *S. taeniocnemis*.

STEPHEN R. GOLDBERG, Department of Biology, Whittier College, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu); **CHARLES R. BURSEY**, Department of Biology, Pennsylvania State University, Shenango Campus, Sharon, Pennsylvania 16146, USA (e-mail: cxb13@psu.edu).

***SCELOPORUS TRISTICHUS* (Plateau Fence Lizard) and *SCELOPORUS MAGISTER* (Desert Spiny Lizard). PREDATION.** On 25 August 2011 at 1838 h along the Virgin River in Zion National Park, Kane Co., Utah (37.205827°N, 112.978917°W, elev. 1211 m), one of us (CG) observed, photographed, and recorded video of an adult male *Sceloporus tristichus* predating a hatchling *S. magister* (*sensu* Leaché and Mulcahy 2007. Mol. Ecol. 16:5216–5233). The hatchling was being consumed tail-end first and being beat against a rock several times while in mouth of the adult *S. tristichus*. These two species commonly co-occur along stream habitats in Utah (Tinkle 1976. Herpetologica 32:1–6). There have been accounts of *S. consobrinus* (as *S. undulatus hyacinthinus*) predating other lizards in captivity (Groves 1971. J. Herpetol. 5:205), and also cannibalism within *S. magister* (Cardwell 1994. Herpetol. Rev. 3:121–122). However, this is the first published account of *S. tristichus* predating *S. magister*.

Digital video of this predation event is available. For those interested please contact the lead author.

FIG. 1. Adult male *Sceloporus tristichus* consuming a hatchling *S. magister* tail-end first.

***SPHENOMORPHUS INCOGNITUS* (Brown Forest Skink). PARENTAL CARE.** Parental care is common in some terrestrial vertebrates, such as birds and mammals, but is much rarer in reptiles. About 140 reptile species have been reported to exhibit parental care, but many of these records are unconfirmed due to a lack of direct evidence of such behavior (Huang 2006. Anim. Behav. 72:791–795). Crocodilians are the most well-documented group of reptiles that provide parental care (Shine 1988. *In* C. Gans and R. B. Huey [eds.], Biology of the Reptilia, Volume 16, Ecology B: Defense and Life History, pp. 275–329. Alan R. Liss, New York), but relatively few squamate reptiles exhibit such behavior (Huang 2006, *op. cit.*, Huang and Wang 2009. Ethology 115:273–279; O'Connor and Shine 2004. Anim. Behav. 68:1361–1369). Here we describe an observation of nest defense, a form of parental care, by the skink *Sphenomorphus incognitus*.

Sphenomorphus incognitus is a small (ca. 8 cm SVL), surface-dwelling skink distributed from southern China to Taiwan. This oviparous skink produces 3–6 eggs per clutch, and reproduces from spring to summer (Huang 2010. Zool. Stud. 49:779–788). On

PHOTO BY I. C. RO

FIG. 1. Brown Forest Skink (*Sphenomorphus incognitus*) biting a Taiwanese Kukri Snake (*Oligodon formosanus*).

28 August 2008 at 1600 h on Orchid Island, Taitung County, Taiwan (22.0333°N, 121.5666°E), we observed a female *S. incognitus* (8.5 cm SVL) defending its nest from predation by a Taiwanese Kukri Snake (*Oligodon formosanus*; 41 cm SVL). *O. formosanus* is a reptile egg specialist, and regularly eats the eggs of other skink species in the area (e.g., *Eutropis longicaudata*; Huang 2006, *op. cit.*). Female *E. longicaudata* commonly protect their eggs from predation by viciously attacking *O. formosanus*, which causes the snake to leave the nest site (Huang 2006, *op. cit.*). In the current observation, we observed the snake attempting to eat a clutch of *S. incognitus* eggs buried in the soil. The female *S. incognitus* bit the snake at mid body several times over a period of a few minutes (Fig. 1), and by doing so was presumably attempting to deter the snake from eating the eggs. However, this attempt was unsuccessful, because after digging up the nest we discovered that the entire clutch had been eaten by the snake. Despite our long-term studies on Orchid Island (2001–2010), this is our first observation of *S. incognitus* defending a nest from predation. Unlike *E. longicaudata* (which reaches a SVL of ca. 12 cm), the smaller *S. incognitus* was unable to protect its eggs from snake predation, possibly because the snake was undeterred by bites from such a small skink. We suspect that this skink had recently laid the eggs, and was still in the area when the snake predated the nest, explaining the absence of other observations of similar behavior. Otherwise, most oviparous squamates bury their eggs, which makes it difficult to document instances of parental care.

***TROPIDURUS HISPIDUS* (Calango). SAUROPHAGY.** *Tropidurus hispidus* has a wide geographical distribution, mainly in open landscapes of northeastern South America (Rodrigues 1987. Arq. Zool. 31:105–230). *T. hispidus* is considered a generalist predator that preys on several arthropod taxa as well as plant items (Kolodiuk et al. 2010. S. Am. J. Herpetol. 5:35–44; Van Sluys et al. 2004. J. Herpetol. 38:606–611; Vitt 1995. Occ. Pap. Oklahoma Mus. Nat. Hist. 01:01–29; Vitt et al. 1996. J. Trop. Ecol. 12:81–101).

Among tropidurids, saurophagy has been recorded for *T. montanus* (Kiefer and Sazima 2002. Herpetol. Rev. 33:136), *T. torquatus* (Galdino and Van Sluys 2004. Herpetol. Rev. 35:173), and *T. hygomi* (Kohlsdorf et al. 2004. Herpetol. Rev. 35:398). Herein, we report the predation of *Cnemidophorus ocellifer* by *T. hispidus*.

Observations were made during an ecological study on reproduction and diet of *C. ocellifer* in São Gonçalo do Amarante municipality, west coast of Ceará, northeastern Brazil (3.30495°S, 38.55127°W), where specimens of *C. ocellifer* were collected. On 29 July 2010, at ca. 0830 h, one of us (DZ) hit an individual of *C. ocellifer* (ca. 50 mm SVL) of unknown sex using an air gun (the lizard was stunned momentarily and then ran away). During its attempted escape, the *C. ocellifer* was detected by an adult male *T. hispidus* (ca. 100 mm SVL), which attacked the right side of its body, grabbing almost the entire lizard, with only the head and tail protruding from its mouth. Swallowing lasted for ca. 1 min., the resulting ingestion of the prey oriented tail-first.

This report indicates that *T. hispidus* is a potential predator of *C. ocellifer*, contributing to the knowledge of the ecology of both species in a coastal region of northeastern Brazil. Moreover, this record contributes to the notion that lizards are important components of their ecosystems, acting as predators of other vertebrate species (Rocha and Vrcibradic 1998. Ciência e Cultura 50:364–368).

We thank Conrado A. B. Galdino for providing valuable suggestions on the manuscript, and the Instituto Chico Mendes de Conservação da Biodiversidade for the permit to collect the animals (license #21963-1). DZ also thanks the Fundação Cearense de Apoio ao Desenvolvimento Científico e Tecnológico (BMD-0008-00060.01.14/10) and Coordenação de Aperfeiçoamento de Pessoal de Nível Superior for grant received.

***TROPIDURUS HISPIDUS* (Peters' Lava Lizard). SLEEP-SITE FIDELITY.** Little attention has been given to the study of sleep, despite its essential role in the lives of lizards. The behavior of species during sleep has important implications in their natural history traits, such as predator avoidance, fitness related with proximity to feeding or basking sites, restorative functions, and partitioning of adequate microhabitats (Singhal et al. 2007. Behavior 144:1033–1052; and references therein). Information on sleep-site fidelity (SSF) is even more scarce, and has been reported in less than a dozen species of lizards (Singhal et al., *op. cit.*). Herein, we report on some observations of SSF in the lizard *Tropidurus hispidus*, a tropidurid distributed from northeastern South America to the northeastern and central-eastern regions of Brazil (Rodrigues 1987. Arq. Zool. 31:105–230).

Observations took place at the authors' house in the city of Fortaleza, State of Ceará, northeastern Brazil. Since we have resided at this house in August 2009, lizard residents (*T. hispidus*; *Hemidactylus mabouia*) have pacifically occupied their space. During this period observations *ad libitum* have been made on their behavior, leaving them undisturbed whenever possible. Measurements (snout–vent length and tail length) were calculated with the program ImageJ (Abramoff et al. 2004. Biophotonics Internacional 11:36–42) based on photographs we have taken. Although no individual was marked, daily contact enabled us to differentiate among individuals. From November 2009 to May 2011 four different individuals of *T. hispidus* were observed to display SSF. Observations were distributed between at least 3 months from one another and individuals' site fidelity ranged from 5 to 20 days, after which they were no longer seen. Size of these four lizards ranged from 54.73–101.89 mm and perch height from 1.6–3 m. Sleeping sites were usually behind objects, usually poorly hidden, although one individual used a conspicuous spool of string as perch. In all observations, individuals would maintain the exactly same site for the duration they used it, occasionally changing only the direction they were facing. On two occasions individuals left the sleep-site upon being disturbed, although in both cases they returned the following day to the same perch. Among tropidurid lizards, SSF has only been reported in *T. albemarlensis* from the Galápagos (Stebbins et al. 1967. Ecology 48:839–851). An important factor when choosing sleep sites is the risk of predation (Lima et al. 2005. Anim. Behav. 70:723–736). The use of exposed and poorly hidden sites in the present report indicates that lizards have become aware of their low risk situation, thus choosing circumstances they would probably avoid in nature. We hope these observations will serve as baseline data, aiding in future studies on the largely unknown study of sleep in lizards.

LUCAS B. DE MATTOS BRITO, Laboratório de Zoologia Experimental, Universidade Federal do Ceará, Fortaleza, Ceará, Brazil (e-mail: lucasmb15@yahoo.com); **MARCIONÍLIA F. PIMENTEL,** Laboratório de Ecotoxicologia Marinha, LABOMAR-UFC, Fortaleza, Ceará, Brazil.

***UROSAURUS ORNATUS WRIGHTI* (Northern Tree Lizard). NEMATODE PARASITE.** Examinations of *Urosaurus ornatus* from Arizona, New Mexico, and Texas have recorded three species of nematodes: *Parathelandros texanus*, *Spauligodon giganticus*, and larva of *Physaloptera* sp. (Goldberg et al. 1993. J. Helminthol. Soc. Washington 60:118–121; Specian and Ubelaker 1974. Trans. Amer. Microsc. Soc. 93:413–415). Herein we report a new distributional record for a nematode parasite of *U. ornatus*.

Four adult *U. o. wrighti* (two males, two females, SVL = 41–53 mm) were collected in mid-May 2011 by hand from 9.0 km S of US 191 on St. Hwy 279 at Williams Bottom Campground, Grand Co., Utah, USA (39.08579°N, 109.759167°W). Their feces were examined for coccidian and helminth parasites. Lizards were killed with an overdose of sodium pentobarbital and fecal pellets were removed from their rectum and placed in individual vials of 2.5% (w/v) aqueous potassium dichromate. Feces were concentrated by flotation according to previous methods (McAllister et al. 1991. J. Parasitol. 77:910–913) using Sheather's sugar solution (specific gravity = 1.30). Specimens were examined using a compound microscope.

No coccidian oocysts were found, but a single nematode was recovered from a 52 mm SVL male *U. o. wrighti*, placed in 70% ethanol, and cleared on glass slides with undiluted glycerol. It was subsequently identified as a male *Parathelandros texanus*. A voucher specimen was deposited in the United States National Parasite Collection (USNPC), Beltsville, Maryland as USNPC 104871. A host voucher is deposited in the Arkansas State University Herpetological Collection (ASUMZ), State University, Arkansas as ASUMZ 31775.

Parathelandros texanus was originally described from the Big Bend Canyon Lizard (*Sceloporus merriami annulatus*) from Brewster County, Texas (Specian and Ubelaker, *op. cit.*). Other hosts (all from Arizona, New Mexico, or Texas) include the Gray-checkered Whiptail (*Aspidoscelis dixoni*), Gila Spotted Whiptail

(*A. flagellicauda*), Texas Spotted Whiptail (*A. gularis gularis*), Trans-Pecos Striped Whiptail (*A. inornata heptagramma*), Plateau Spotted Whiptail (*A. septemvittata septemvittata*), Colorado Checkered Whiptail (*Aspidoscelis tesselata*), Western Marbled Whiptail (*Aspidoscelis tigris marmorata*), Southwestern Earless Lizard (*Cophosaurus texanus scitulus*), Canyon Lizard (*Sceloporus merriami*), and Eastern Fence Lizard (*S. undulatus, sensu lato*) as well as previously mentioned *U. ornatus* (Goldberg et al. 1995. J. Helminthol. Soc. Washington 62:188–196; McAllister 1990a. J. Wildl. Dis. 26:139–142; McAllister 1990b. Texas J. Sci. 42:381–388; McAllister et al. 1991. Texas J. Sci. 43:309–314; McAllister 1992. Texas J. Sci. 44:233–239; McAllister et al. 1995. Texas J. Sci. 47:83–88; McAllister et al. 2003. Texas J. Sci. 55:307–314; Specian and Ubelaker, *op. cit.*; Walker and Matthias 1973. Proc. Helminthol. Soc. Washington 40:168–169).

In conclusion, the geographic range of *P. texanus* now includes Arizona, New Mexico, Texas, and Utah (new distributional record) and at least 12 species of lizard hosts within two families (Phrynosomatidae, Teiidae). We expect additional hosts and localities for *P. texanus* will be reported with future surveys of lizards.

SQUAMATA — SNAKES

***ARIZONA ELEGANS ELEGANS* (Kansas Glossy Snake). DIET AND FEEDING BEHAVIOR.** *Arizona elegans elegans* is known to prey upon lizards and small mammals (McKinnney and Ballinger 1966. Southwest. Nat. 11:410–412). *Dipodomys ordii* (Ord's Kangaroo Rat) is a known prey species of *A. elegans* (Rodríguez-Robles 1999. J. Herpetol. 33:87–92). In a literature review of carrion foraging in snakes, Devault and Krochmal (2002. Herpetologica 58:429–236) did not identify *A. elegans* as a scavenger. Herein we report the first observation of *A. elegans* foraging on a road-killed *D. ordii*.

On 12 June 2010, at 2300 h, we observed an *A. elegans* (SVL = 585 mm; total length = 694 mm) consuming a road-killed *D. ordii* (Fig. 1) on Highway 249, Chavez Co., New Mexico, USA (33.0185°N, 103.8723°W, datum: WGS 34; elev. 1320 m). To prevent the snake from being killed by oncoming traffic, we gently moved it to the south shoulder of the highway. Rodrigues-Robles et al. (*op. cit.*) investigated the stomach contents of approximately 700 museum specimens of *A. elegans*. Of the 107 prey items recovered, 43.9% were mammals. However the design of their study did not allow them to determine the disposition of the prey prior to consumption. Devault and Krochmal's (2002, *op. cit.*) literature review suggests that carrion foraging in snakes should not be considered unusual, however it was unclear until this observation if *A. elegans* could be counted among the snakes known to consume carrion in the wild.

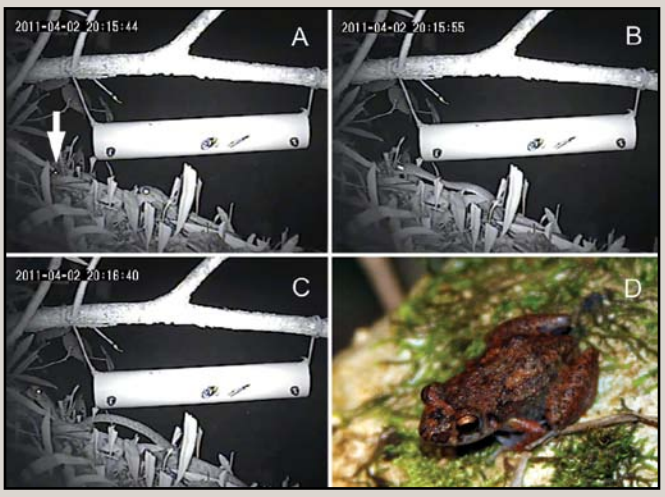

FIG. 1. *Arizona elegans elegans* consuming a road killed *Dipodomys ordii*. Note the rodent's viscera, confirming that it was a road kill.

***BOIGA IRREGULARIS* (Brown Treesnake). DIET.** The invasive *Boiga irregularis*, having decimated most of the native species it preyed on in Guam, now preys heavily on other invasive vertebrates. *Eleutherodactylus planirostris* (Greenhouse Frog), which has recently become established on Guam (Christy et al. 2007. Pac. Sci. 61:469–483), may provide the snake with an additional food source because the frogs are active nocturnally and can attain high densities (12,500 frogs ha^{-1} in Hawaii; Olson 2011. Unpubl. dissertation. Utah State University, Logan. 116 pp.). *Boiga irregularis* consume *E. planirostris* in captivity (unpubl. data in Christy et al. 2007. Pac. Sci. 61:469–483), but it is unknown whether they take them in the field. Others have suggested that *B. irregularis* are unlikely to prey upon anurans because of learned avoidance after attempting to take a poisonous species, *Bufo marinus*, which is also introduced and common throughout Guam.

On 2 April 2011, during the course of video recording of nocturnal snake activity in roadside vegetation at U.S. Naval Computer and Telecommunications Station Guam (13.574758°N, 144.834967°E; datum WGS84), we observed two *E. planirostris* moving about on a moss and fern-covered log approximately 1 m above the forest floor. This location is approximately 7.7 km north of the discovery site for this recently-arrived species (Christy et al., *op. cit.*) At 2015 h, a juvenile Brown Treesnake (ca. 600 mm SVL) appeared on the side of the log approximately 10 cm from one of the frogs, which quickly leapt off of the log. The snake

PHOTOS BY TOM MATHIES

FIG. 1. *Boiga irregularis* feeding sequence on an *Eleutherodactylus planirostris*, northern Guam, USA. A. Snake approaches frog (arrow indicates eye-shine of frog); B. Snake lunging toward frog. C. Snake swallowing frog; D. *Eleutherodactylus planirostris* at study site.

rapidly swung around to face the direction of the departed frog, but did not follow. Soon after, the second frog emerged from cover and took a few steps toward the snake (Fig. 1A). The snake then moved toward the frog, paused, and then lunged at the frog (Fig. 1B), catching it in its mouth and consuming it immediately thereafter (Fig. 1C). To verify whether the frogs on our video recording were *E. planirostris*, we returned to the site the following night. A cursory visual search of a 1.5 × 4.5 m strip of forest floor beneath the log revealed approximately 15 small *E. planirostris* (Fig. 1D). If juvenile *B. irregularis* are taking substantial numbers of frogs as prey, the snake may become more difficult to control than at present. Moreover, large populations of *E. planirostris* (both on Guam and elsewhere) may facilitate the establishment of *B. irregularis* in new areas, such as Hawaii or other Pacific Islands.

TOM MATHIES, U.S. Department of Agriculture, Animal Plant Health Inspection Service, Wildlife Services, National Wildlife Research Center, 4101 LaPorte Avenue, Fort Collins, Colorado 80521-2154, USA (e-mail: tom.c.mathies@aphis.usda.gov); **WILLIAM C. PITT**, U.S. Department of Agriculture, Animal Plant Health Inspection Service, Wildlife Services, National Wildlife Research Center, PO Box 10880, Hilo, Hawaii 96721, USA (e-mail: Will.Pitt@aphis.usda.gov); **JOSEPH A. RABON**, U.S. Department of Agriculture, Animal Plant Health Inspection Service, Wildlife Services, 233 Pangelinan Way, Barrigada, Guam 96913, USA (e-mail: Joseph.A.Rabon@aphis.usda.gov).

***BOTHROPS JARARACUSSU* (Jararacussu). DIET.** The South American pitviper *Bothrops jararacussu* is a large viperid, reaching up to 1.8 m in length, and is known to feed on small mammals, amphibians, and reptiles (Martins et al. 2002. *In* Schuett et al. [eds.] Biology of Vipers, pp. 307–328. Eagle Mountain Publ., Eagle Mountain, Utah). On 1 January 2011, we found a Brazilian squirrel, *Guerlinguetus ingrami* (33 cm; 150 g) in the process of being ingested by a female *B. jararacussu* (total length = 110 cm). The snake was found in the afternoon (1700 h) in the middle of a dirt road, near a secondary forest fragment in the municipality of Cascavel, Paraná, south Brazil. This location is part of Araucarian Forest (Atlantic Forest; Castella and Britez 2004. A Floresta com Araucária no Paraná. MMA Publ., Brasília. 233 pp.) and is in close proximity to a river. When approached the snake regurgitated the squirrel and tried to escape. To our knowledge, this is the first record of *B. jararacussu* preying on a *G. ingrami*. This observation is particularly interesting, given that *B. jararacussu* is terrestrial and primarily feeds on terrestrial prey (Martins et al. 2001. J. Zool. 254:529–538; Martins et al. 2002, *op. cit.*; Hartmann et al. 2009. Pap. Avul. Zool. 49:343–360), whereas *G. ingrami* is primarily arboreal (Bordignon and Monteiro-Filho 1997. Rev. Bras. Zool. 14:707–722; Bordignon and Monteiro-Filho 2000. Can. J. Zool. 78:1732–1739).

We thank Gilmar Manica and João Silva for field snake handling, which allowed identification of the snake; DV Andrade for critical reading; CNPq, for financial support to CRB and FAPESP, for financial support to RSBG.

***CHRYSOPELEA PARADISI* (Garden Flying Snake). DIET.** *Chrysopelea paradisi* is a common lowland snake in Southeast Asia (Inger and Stuebing 1999. A Field Guide to the Snakes of Borneo. Natural History Publications, Sdn Bhd, Kota Kinabalu. viii + 254 pp.), and a known predator of gekkonid lizards (Das 2010. A Field Guide to the Reptiles of Southeast Asia. New Holland Publishers Ltd., London. 376 pp.), the agamid *Bronchocela cristatella* (Lim and bin Peral 1959. Malayan Nat. J. 14:33–34), the scincid *Lamprolepis smaragdina philippinica* (Gaulke 1986. Salamandra 22:211–212), and the bamboo bat, *Tylonycteris* sp. (Leong and Foo 2009. Nature in Singapore 2:311–316).

On 30 December 2009, at ca. 1200 h, a *C. paradisi* was observed on a concrete walking path at the Piasau Boat Club (04.436541°N, 113.996485°E, datum: WGS84), Miri, Sarawak, East Malaysia. It was tightly coiled around a small struggling arboreal scincid lizard, *Apterygodon* [*Dasia*] *vittatum*, recognizable by the robust body shape and distinctive stripes along the head. This particular specimen had a truncated tail, presumably lost in a prior (near) predation event.

Over a period of ca. 10–15 min, the snake remained almost stationary, apparently constricting the skink, whose movements gradually became more erratic and less frequent. When the movements had almost ceased altogether, the snake changed position, and maneuvered the skink to begin consuming the skink head-first (Fig. 1). Once consumption started, less than a minute elapsed before the entire skink was swallowed.

FIG. 1. *Chrysopelea paradisi* ingesting an *Apterygodon vittatum* in Sarawak, East Malaysia.

***CROTALUS CERBERUS* (Arizona Black Rattlesnake). DIET.** *Crotalus cerberus* is a denizen of mesic environments in higher-elevation regions of Arizona and western New Mexico (Brennan and Holycross 2006. A Field Guide to Amphibians and Reptiles in Arizona. Arizona Game and Fish Dept., Phoenix. 150 pp.). Prior to being recognized as a separate species from *C. viridis* [*oreganus*], it was presumed that *C. cerberus* was an opportunistic predator, taking a variety of prey taxa (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque, New Mexico. 433 pp.; Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Inst. Press, Washington, DC. 668 pp.). Since being distinguished from *C. viridis*, its

diet has been documented to include lizards, including *Sceloporus* [*undulatus*] *tristichus* (Schuett et al. 2002. Herpetol. Rev. 33:210–211). Here, based on one of the first field studies of free-ranging *C. cerberus*, we present new information on prey use at a low-elevation site in Arizona.

From 2004 to 2008 we conducted radio-telemetry on sympatric *C. cerberus*, *C. atrox*, *C. molossus*, and *Heloderma suspectum* at Tonto National Monument, Gila Co., Arizona, USA. The site is characterized by steep rocky slopes, bajadas, and dry washes with upland Sonoran desertscrub, with elevations ranging from 695–1230 m. We documented prey use through blunt dissection of scats opportunistically collected when an animal defecated (Quick et al. 2005. J. Herpetol. 39:304–307). We also documented prey use from regurgitated prey items and through direct observation of predation.

Prey use was documented for three telemetered adult male *C. cerberus* from six separate feeding events. Through scat dissection, four distinct prey were identified: one unidentified bird (based on feather remains); two rodents (Cactus Mouse, *Peromyscus eremicus*; and Harris' Antelope Squirrel, *Ammospermophilus harrisii*); and one lizard (*Sceloporus* sp., likely *S. magister*). Importantly, four prey types (and therefore feeding events) were found in three scats of our subjects, indicating that a single scat may represent more than one feeding event. One male consumed the bird, the *P. eremicus*, and the *Sceloporus* sp.; of these, the mouse and lizard remains were found in the same scat. Two direct feeding observations were also made. One individual regurgitated a *Neotoma albigula* (White-throated Woodrat) after being captured on 14 July 2003, and was thought to contain a separate meal that was not regurgitated (J. Schofer, pers. obs.). A different adult male was observed consuming an adult Ash-throated Flycatcher (*Myiarchus cinerascens*) during a routine telemetric location on 5 June 2004 (A. Madara-Yagla, photo voucher).

Given the prey taxa documented for *C. cerberus* at this site, the species appears to be an opportunistic predator, supporting previous assessments. An apparent lack of lagomorphs in *C. cerberus* diet compared to other venomous species at the site (Nowak 2009. Unpubl. PhD dissertation. Northern Arizona University, Flagstaff, Arizona.) might reflect habitat partitioning (Beck 1995. J. Herpetol. 29:211–223) with other rattlesnakes, or it may reflect differences in body and gape size among the species (Klauber 1972. Rattlesnakes: Their Habits, Life Histories, and Influence on Mankind. Univ. California Press, Los Angeles. 1533 pp.). Nevertheless, the wide variety of prey types consumed by *C. cerberus* suggests that this species may play an important mesopredator role in certain ecosystems (Nowak et al. 2008. Biol. Rev. 83:601–620).

Support for our research was provided by the National Park Service, the Western National Parks Association, and the J. W. Prather Memorial Scholarship. Assistance was provided by M. Cardwell, E. Dugan, L. Gilmore, H. E. Graham, M. Hamilton, A. Madara-Yagla, K. Nishikawa, J. Schofer, the staff of Tonto National Monument, and numerous volunteers. M. Cardwell, J. Ennen, J. Lovich, P. Salo, C. Spencer, and anonymous reviewers offered comments on earlier drafts.

CALEB L. LOUGHRAN (e-mail: cloughran@usgs.gov), **ERIKA M. NOWAK** (e-mail: Erika.Nowak@nau.edu), and **ROBERT W. PARKER** (e-mail: parkeranywhere68@hotmail.com), U.S. Geological Survey and Colorado Plateau Research Station, Northern Arizona University, Applied Research & Development Bldg., Suite 150, Flagstaff, Arizona 86011, USA.

***CROTALUS MOLOSSUS MOLOSSUS* (Northern Black-tailed Rattlesnake). DIET.** *Crotalus molossus* is a large-bodied rattlesnake whose dietary habits have been fairly well documented (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. 433 pp.; Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Inst. Press, Washington, DC. 668 pp.). Small mammals are most frequently consumed; however birds also comprise a portion of its diet (16.7%; Reynolds and Scott 1982. *In* N. J. Scott, Jr. [ed.], Herpetological Communities, pp. 99–118. U.S. Fish and Wildlife Service, Widl. Res. Rep. 13.) Though birds have been documented in the diet, which bird species are actually consumed is largely unknown. From 2004 to 2008 we conducted radio-telemetry studies on sympatric *C. molossus*, *C. atrox*, *C. cerberus*, and *Heloderma suspectum* at Tonto National Monument, Gila Co., Arizona, USA. Based on results from this study, we present a new dietary record for *C. molossus*.

Prey use was documented for a single, telemetered adult male *C. molossus* (SVL = 100 cm; 675 g) using scat dissection (Quick et al. 2005. J. Herpetol. 39:304–307). Two scats were collected from this individual; one on 26 March 2006 and one on 29 March 2006. Both scats contained feathers from a passerine bird, which was later identified as a Black-throated Sparrow (*Amphispiza bilineata*). No other remains were found in either scat. Because both scats were collected within one week of each other, it is likely that the remains in the scats represent the same prey item. To our knowledge, these observations represent the first record of predation by *C. molossus* on *A. bilineata*.

Support for our research was provided by the National Park Service, the Western National Parks Association, the J. W. Prather Memorial Scholarship, and by the US Geological Survey. T. Theimer identified the bird feathers.

PARKER** (e-mail: parkeranywhere68@hotmail.com), U.S. Geological Survey, Colorado Plateau Research Station, Northern Arizona University, Applied Research & Development Bldg., Suite 150, Flagstaff, Arizona 86011, USA.

***CROTALUS MOLOSSUS* (Black-tailed Rattlesnake). RAIN HARVESTING BEHAVIOR.** Opportunistic water gain from rain, sleet, dew, fog, or snow seems to be an adaptive strategy utilized by many reptiles in desert habitats, where accumulation of rain water on ground surfaces is infrequent (Sherbrooke 1990. J. Herpetol. 24:302–308). To date, there is a single documented episode of *C. molossus* drinking rainwater from a rock surface (Greene 1990. Pacific Discovery 43:10–19). Herein, we report the first observation of *C. molossus* consuming water from its own body during a rainstorm in the Chihuahuan Desert of west Texas.

On 26 June 2010, at 1840 h, we radio tracked an adult male *C. molossus* (SVL = 1000 mm; tail length = 80 mm; 820.0 g) as part of an ongoing study of rattlesnake spatial ecology at the Indio Mountains Research Station, Hudspeth Co., Texas, USA (30.770480°N, 105.013491°W, datum: WGS84; elev. 1221 m). The snake was located, prior to a rainfall event, in a coiled position on a rocky slope (10° angle) with its head pointing downward and its snout in contact with the lateral surface of the body. It began to rain and subsequently the snake was able to harvest water flowing off the tilted lateral mid-body section (Fig. 1). The rattlesnake continued consuming water during the entire rainfall episode (ca. 25 min.). Unlike previous reports of rain harvesting behavior by other rattlesnakes (e.g., Aird and Aird 1990. Bull. Chicago Herpetol. Soc. 25:217; Cardwell 2006. Herpetol. Rev. 37:142–144; Glaudas 2009. Southwest. Nat. 54:515–521), the *C. molossus* did not use its tongue to lick water from a dorsally

FIG. 1. An adult male *Crotalus molossus* harvesting water from its body at Indio Mountains Research Station, Hudspeth Co., Texas, USA.

flattened body section. We presume that the rattlesnake did not need to flatten its body to collect water due to constant flow from the ongoing rainstorm. After rainfall ceased, the rattlesnake continued harvesting water from the wet body surface, but in due course stopped and then crawled into a rock crevice.

We thank H. W. Greene who kindly provided information regarding literature sources.

VICENTE MATA-SILVA (e-mail: vmata@utep.miners.edu), **JERRY D. JOHNSON**, and **ARTURO ROCHA**, Department of Biological Sciences, University of Texas at El Paso, El Paso, Texas 79968, USA.

***ELAPOMORPHUS QUINQUELINEATUS* (Raddi's Lizard-eating Snake). DIET.** The rear-fanged *Elapomorphus quinquelineatus* is known to prey on other burrowing snakes and amphisbaenians (Greene 1997. Snakes: the Evolution of Mystery in Nature. Univ California Press, Berkeley. 351 pp.). On 3 February 2011, at 1800 h, an adult female *E. quinquelineatus* (SVL = 912 mm, tail length = 87 mm; 170 g) was found preying on adult male *Amphisbaena microcephala* (IBSP CRIB 0114; SVL = 440 mm; tail length = 25 mm; 108 g) in a backyard of Núcleo Residencial/Instituto Butantan, close to a remnant of secondary Atlantic Forest in São Paulo City, Brazil (23.34143°S, 46.43031°W, datum WGS84; 730 m elev.). After being collected, the snake voluntarily regurgitated the freshly killed amphisbaenian, which had been ingested head first and displayed spreading hemolytic signs in the gular region (Fig. 1). The prey/predator mass ratio was 0.63. To my knowledge, this is first record of *A. microcephala* in the diet of *E. quinquelineatus*. The snake was kept in captivity at Laboratório de Herpetologia, Instituto Butantan, São Paulo, Brazil.

FIG. 1. *Elapomorphus quinquelineatus* with an *Amphisbaena microcephala* that it had consumed.

MARCELO RIBEIRO DUARTE, Laboratório de Herpetologia, Instituto Butantan, Av. Vital Brazil, 1500, CEP 05503-900, São Paulo, SP, Brazil; e-mail: mrduarte@butantan.gov.br.

***ERYTHROLAMPRUS AESCULAPII* (Southern Mock Coralsnake). DIET AND PREY SIZE.** On 23 June 2008, at 1330 h, an adult female *Erythrolamprus aesculapii* (total length = 711 mm; 56 g after prey regurgitation) was caught next to a lake, in an anthropogenic habitat at The Instituto Cultural Inhotim, Brumadinho municipality, in Minas Gerais State, Brazil (27.125°S and 44.220°W, datum WGS84). While being handled, the snake, which appeared to have fed recently, regurgitated an adult female *Liophis poecilogyrus* that was longer and heavier than itself (total length = 803 mm, 85 g). A study on the diet and feeding behavior of *E. aesculapii* (Marques and Puorto 1994. Rev. Bras. Biol. 54:253–259), did not record *E. aesculapii* consuming snake prey greater than their own body weight. Sazima and Martins (1990. Mem. Inst. Butantan 52:73–79) reported juvenile snakes unsuccessfully attempting to ingest very large prey, a behavior that results in energy waste and increases the risk of injuries and predation. However, the small diameter of an elongated prey item (such as another snake) may alleviate gape limitation, allowing consumption of very large prey. To our knowledge, the relative size of this prey item (152% of predator mass) is the largest reported for *E. aesculapii* and is among the largest reported for snakes in general. Both snakes were deposited in the herpetological collection of the Museu de Ciências Naturais of Pontifícia Universidade Católica de Minas Gerais (MCNR 3751, MCNR 3750), in Belo Horizonte, State of Minas Gerais, Brazil.

We thank Ivan Sazima for reviewing this manuscript.

ANTÔNIO M. LINARES (e-mail: bioantonio1@yahoo.com.br) and **PAULA C. ETEROVICK** (e-mail: eterovick@yahoo.com), Programa de Pós-Graduação em Zoologia de Vertebrados, Pontifícia Universidade Católica de Minas Gerais, 30535-610, Belo Horizonte, Minas Gerais, Brazil.

***GEOPHIS MUTITORQUES* (Highland Earth Snake). REPRODUCTION.** *Geophis mutitorques* is known from the Sierra Madre Oriental of the northeastern México; recorded from the highlands of San Luis Potosí, Hidalgo, Puebla, and Veracruz (Downs 1967. Misc. Publ. Mus. Zool. Univ. Michigan 131:1–193; Wilson and Townsend 2007. Zootaxa 1395:1–31). The natural history of this species is poorly understood and no data on reproduction are available. On 15 March 2011, three gravid female *G. mutitorques* (CIB 4121–4123) were collected in cloud forest habitat at the community El Xoté, Municipality Tenango de Doria, Hidalgo, México (20.2054°N, 98.160270°W, datum WGS84; elev. 1506 m). One female (CIB 4121) measured 384.7 mm SVL, body mass 30.0 g, with a clutch size of 6 eggs, and a total egg mass of 4.03 g; the second female (CIB 4122) measured 406.6 mm SVL, body mass 35.0 g, with a clutch size of 5 eggs, and a total egg mass of 3.89 g; and the last female (CIB 4123) measured 365.6 mm SVL, body mass 21.0 g, with a clutch size of 3 eggs, and a total egg mass of 1.09 g. This information is the first record of clutch size for *G. mutitorques* from cloud forest habitat.

This study was supported by the projects CONACYT-S 52552-Q and FOMIX-HGO-2008-95828 "Diversidad Biológica del Estado de Hidalgo."

***LIOPHIS ALMADENSIS* (Almaden Ground Snake). PREDATION.** Snakes are an important component of the diet of many mammals, birds, anurans, crocodilians, lizards, other snakes, and even invertebrates (Costa et. al. 2009. Rev. Bras. Zool. 11:171–173; Mattison 1995. Cassel Paper. 256). Here we report the successful predation on a young *Liophis almadensis* (SVL = 240 mm) by a *Leptodactylus vastus* (Northeastern Pepper Toad; SVL = 148 mm). The predation event was observed on 10 October 2010, at 2132 h, in the U.C. Wildlife Refuge Mata do Junco (10.291037°S, 36.583701°W; datum: SAD 69), in the city of Capela, Sergipe, Brazil. The toad was found in a "clean field" (pasture), approximately 1 m from the margin of a temporary pond, with the snake in its mouth (Fig. 1). The snake was still moving, indicating that it had been attacked shortly before the viewing, and exhibited small wounds on the posterior regions. The anuran and the snake were both deposited in the Herpetological Collection of the Federal University of Sergipe (CHUFS C 1037 and C 1256).

We thank Luiz Gustavo Borges for revision of the text and Frederico Gustavo R. França for confirming identification of the snake, the Secretary of Environment and Hydrological Resources – SEMARH/S for providing the collecting license (2010.05.0102/00101-001), and the Federal University of Sergipe for logistical support.

FIG. 1. *Leptodactylus vastus* found preying upon a young *Liophis almadensis* in Capela, Sergipe, Brazil.

***LIOPHIS MILIARIS* (Watersnake). DIET.** *Liophis miliaris* is a semi-aquatic snake that is widely distributed in cisandean South America (Dixon 1989. Smithson. Herpetol. Inf. Serv. 79:1–28). Judging from records in the literature, this snake preys mainly on anurans (Hartmann et al. 2009. Pap. Avul. Zool., São Paulo 49:343–360; Marques and Sazima 2004. *In* Marques and Duleba [eds.], Estação Ecológica Juréia-Itatins. Ambiente Físico, Flora e Fauna, pp. 257–277. Holos, Ribeirão Preto; Michaud and Dixon 1989. Herpetol. Rev. 20:39–41). In spite of having semi-aquatic habits, there are few published records of this species feeding on fishes; to our knowledge, only two species of fishes have been reported as prey of *L. miliaris* in natural conditions: *Bathygobius soporator* (Gobiidae) and *Guavina guavina* (Eleotridae) (Marques and Sazima, *op. cit.;* Marques and Souza 1993. Rev. Brasil. Biol. 53:645–648). Lema et al. (1983. Comun. Mus. Ci. PUC-RS, Porto Alegre 26:41–121) also reported a specimen preying on the fish *Gymnotus carapo* (Gymnotidae) in captivity.

In the present note, we report a new prey item for *L. miliaris* based on the stomach contents of a female specimen from the region of Itaipuaçu, in Niterói municipality, state of Rio de Janeiro, Brazil. The snake (adult female; SVL = 455 mm; tail length = 135 mm) was brought to the first author in 2010, but the exact date of collection was unknown. The snake's head and neck region were badly damaged, suggesting that it had been bludgeoned to death. Upon dissection, the snake was found to contain an armored catfish (*Callichthys callichthys*; Callichthyidae) in the esophagus. The fish, which had been swallowed head-first, measured 68.6 mm in length, but was missing the tail (it was probably torn off during the bludgeoning of the snake). The original standard length of the specimen was estimated to be ca. 121 mm based on its head length of 32.5 mm, according to measurements of Lehmann and Reis (2004. Copeia 2004:336–343). The snake and its prey were deposited at the reptile collection of the Universidade Federal do Estado do Rio de Janeiro (UNIRIO 46).

Like other fishes of the Order Siluriformes, *Callichthys callichthys* has spines on the dorsal and pectoral fins which are equipped with friction locking mechanisms that, when activated, keeps them erect (Schaefer 1984. Copeia 1984:1005–1008). The fish was probably manipulated to be swallowed head-first in order to prevent its fin spines from locking, impairing ingestion (Sturaro and Gomes 2008. Bol. Mus. Para. Emílio Goeldi, Ciências Naturais 3:225–228). Also, *C. callichthys* has a body covered by an "armor" of plate-like scales, unlike the other fishes previously reported as prey for *L. miliaris* which are all "soft-bodied." Armored catfishes of the genus *Callichthys* have been previously reported as prey for the aquatic coral snake *Micrurus surinamensis* (Martins and Oliveira 1998. Herpetol. Nat. Hist. 6:78–150). Lema et al. (*op. cit.*) reported a specimen of another aquatic snake (*Helicops infrataeniatus*), which was found coiled around a *C. callichthys* and trying to swallow it, but the authors did not mention if it succeeded in consuming the fish. Aguiar and Di Bernardo (2004. Stud. Neotrop. Fauna Environ. 39:7–14) recorded another species of Callichthyidae (*Corydoras paleatus*) in the diet of *H. infrataeniatus*. The above observations, together with the present record, indicate that the "armored" body and the fin spines of *C. callichthys* and other callichthyids do not completely deter predation by snakes.

DAVOR VRCIBRADIC (e-mail: davor@centroin.com.br), **JULIA NIEMEYER** (e-mail: julia.niemeyer@gmail.com), Departamento de Zoologia, Universidade Federal do Estado do Rio de Janeiro, Av. Pasteur 458, Urca, 22240-290, Rio de Janeiro, RJ, Brazil; **CARLOS AUGUSTO FIGUEIREDO**,

***LIOPHIS POECILOGYRUS* (Yellow-bellied Liophis). DIET AND FORAGING BEHAVIOR.** *Liophis poecilogyrus* is a colubrid snake widely distributed across South America. The species is often associated with mesic habitats, which is reflected in its diet that primarily consists of anurans and fish (Michaud and Dixon 1989. Herpetol. Rev. 20:39–42; Schalk 2010. Herpetol. Rev. 41:366–367). Although its diet has been well documented, other aspects of its natural history (e.g., behavior) are lacking. Here we report an observation on the foraging behavior of a *L. poecilogyrus* on tadpoles of *Leptodactylus bufonius* (Oven Frog).

On 30 December 2010, at 2300 h, we observed a male *L. poecilogyrus* (SVL = 411 mm; tail length = 81 mm; 32 g) foraging in a flooded ditch (approximately 10 m long and 0.5 m wide) in the Isoceño community of Yapiroa (19.60721°S, 62.57492°W; datum WGS 84), Province Cordillera, Department of Santa Cruz, Bolivia. While swimming in the ditch, the *L. poecilogyrus* had its head submerged and its mouth open as it chased and captured tadpoles of *L. bufonius*. When the snake captured a tadpole, it would push and hold the tadpole against the mud until it was able to move its mouth onto the head of the tadpole, after which it was able to swallow the individual. After approximately 30 sec underwater without a successful capture, the *L. poecilogyrus* would stop and raise its head above water and remain completely still. The snake would then plunge its head back underwater, swimming with its mouth agape in areas of the ditch where we observed a high abundance of swimming tadpoles. The snake continued foraging in this manner for an additional ten minutes before it left the ditch. This observation is consistent with other reports of head-first prey ingestion by *L. poecilogyrus* (De Souza et al. 2009. Biota Neotrop. 9:263–269) and also suggests that *L. poecilogyrus* primarily relies on tactile cues to detect and locate its prey while foraging in water.

Funding for this trip was provided by the National Science Foundation's Graduate Research Fellowship Program (awarded to CMS).

CHRISTOPHER M. SCHALK (e-mail: cschalk@tamu.edu), and **CARMEN G. MONTAÑA**, Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, Texas 77843-2258, USA.

***MICRURUS NIGROCINCTUS* (Central American Coralsnake). DIET.** Much remains to be learned about the natural history of many Central American snakes. *Micrurus nigrocinctus* is a relatively common terrestrial and semi-fossorial snake that ranges from southern Mexico to northern Colombia. The diet has been relatively well studied and is known to include caecilians, many lizards, and snakes of the genera *Anomalepis*, *Helmanthophis*, *Typhlops*, *Coniophanes*, *Geophis*, and *Ninia* (Savage 2002. The Amphibians and Reptiles of Costa Rica: a Herpetofauna Between Two Continents, Between Two Seas. Univ. Chicago Press, Illinois. 934 pp.) Solórzáno (2004. Snakes of Costa Rica: Distribution, Taxonomy, and Natural History. Instituto Nacional de Biodiversidad, Santo Domingo de Heredia, Costa Rica. 791 pp.) reports on hundreds of individuals and adds the snake genera *Boa*, *Conophis*, *Dendrophidion*, *Drymobius*, *Enulius*, *Imantodes*, *Masticodryas*, *Rhadinaea*, *Tantilla*, and *Urotheca*.

On 1 February 2011, at 0755 h, an adult *M. nigrocinctus* (SVL = 46.2 cm; US National Museum Field Series #254130) was collected dead on the entrance road to El Copé, Coclé Province, Republic of Panama, between the communities of Las Tibias and El Copé (8.62343°N, 80.57100°W, datum WGS84). The snake was split open and protruding from the body wall was a small black snake identified as *Liotyphlops albirostris* (US National Museum Field Series #254181). The anterior 14.5 cm of the snake was undigested. This is the first dietary record for *M. nigrocinctus* for the Republic of Panama and the first documentation of *L. albirostris* as a prey item for the species.

We thank La MICA Biological Station for logistical support.

KNIGHT**, Savannah River Ecology Laboratory, PO Drawer E, Aiken, South Carolina 29801, USA and The South Carolina State Museum, 301 Gervais Street, Columbia, South Carolina 29202, USA (e-mail: jim.knight@scmuseum.org); **PABLO SANTANA**, La MICA Biological Station, El Copé de La Pintada, Coclé Province, Republic of Panama.

***NERODIA ERYTHROGASTER TRANSVERSA* (Blotched Watersnake). ENDOPARASITES.** Twelve species of trematodes and seven species of nematodes have been reported previously from *Nerodia erythrogaster* (Ernst and Ernst 2006. SSAR Herpetol. Circ. 34:1–86); however, to our knowledge, no pentastomids have been reported from this host. Here we report two new endoparasite records for *N. e. transversa*.

A single adult Blotched Watersnake was obtained from an unknown locale in Harris Co., Texas, USA, and housed at the Houston Zoological Gardens where it remained until it died on 1 June 1992. A midventral incision was made to expose the entire length of the digestive tract. A single larval nematode and four nymphal pentastomids were recovered from dermal cysts and cleared on glass slides with undiluted glycerol. These were subsequently identified as larval *Eustrongylides* sp. (Nematoda) and nymphs of *Porocephalus* sp. (Pentastomida). A voucher specimen of *Eustrongylides* sp. was deposited in the United States National Parasite Collection (USNPC), Beltsville, Maryland as (USNPC 104634). The *Porocephalus* sp. was retained in our personal collection.

Adults of *Porocephalus crotali* Humboldt (Porocephalida: Porocephalidae) have been reported from various crotalids (Forrester et al. 1970. J. Parasitol. 56:977; Nicoli 1963. Ann. Parasitol. Hum. Comp. 38:483–516; Self 1969. Exp. Parasitol. 24:63–119). The life history of this parasite may be similar to the life history of another pentastomid, *Kiricephalus coarctatus* (Diesing), where ophiophagous snakes are the definitive hosts and other snakes can serve as paratenic hosts (Self, *op. cit.*). However, a mammal could be an alternative host (Layne 1967. Bull. Wildl. Dis. Assoc. 3:105–109; Self 1972. Trans. Amer. Micros. Soc. 91:2–8). *Eustrongylides* sp. Jägerskiöld (Trichuridea: Dioctophymatidae) have been reported previously from the stomach, mesenteries, body wall musculature, coelomic cavity, and subcutaneous tissues of several free-ranging and captive snakes, including *Agkistrodon contortrix, Bothrops atrox, Coluber constrictor, Drymarchon couperi, Masticophis flagellum, Nerodia sipedon, Pituophis catenifer, P. melanoleucus, Thamnophis eques, T. sirtalis,* and an unknown species of python (Bursey 1986. J. Wildl. Dis. 22:527–532; Ernst and Ernst, *op. cit.*). *Nerodia erythrogaster transversa* represents a new host record for nymphs of *Porocephalus* sp. and larva of *Eustrongylides* sp.

(e-mail: cxb13@psu.edu); **PAUL S. FREED**, 14149 Butte Creek Road, Scotts Mills, Oregon 97375, USA (e-mail: herps2apes@peoplepc.com).

***NERODIA RHOMBIFER WERLERI* (Diamond-backed Watersnake). ENDOPARASITES.** *Nerodia rhombifer werleri* is known from Veracruz, south through Tabasco and parts of Campeche and Chiapas, Mexico (Gibbons and Dorcas 2004. North American Watersnakes: A Natural History. Univ. Oklahoma Press, Norman. 438 pp.). Parasites of *N. rhombifer* are listed in Gibbons and Dorcas (*op. cit.*) and Ernst and Ernst (2006. Synopsis of Helminths Endoparasitic in Snakes of the United States and Canada. SSAR Herpetol. Circ. 34:1–86). To our knowledge, there are no reports of helminths from *N. r. werleri*. The purpose of this note is to establish the initial helminth list for *N. r. werleri*.

A sample of 38 *N. r. werleri* consisting of 17 females (mean SVL = 600.6 mm ± 114.6 SD, range = 330–740 mm) and 21 males (mean SVL = 614.8 mm ± 93.6 SD, range = 460–758 mm) collected in 1987 by (RDA) near Tlacotalpan (18.6667°N, 95.7500°W, datum WGS84; elev. 10 m), Veracruz, Mexico were examined. Snakes were deposited in the herpetology collection of the Natural History Museum of Los Angeles County (LACM), Los Angeles, California, USA. The body cavity of each snake was opened and the digestive tract was removed, opened by a longitudinal incision, and examined under a dissecting microscope. Food contents of the stomach were previously removed (Aldridge et al. 2003. Herpetologica 59:43–51). In some cases stomach residuum remained, which was examined. One species of Cestoda, and four species of Nematoda were found. Cestodes were regressively stained in hematoxylin, mounted in Canada balsam. Nematodes were cleared in glycerol. All were mounted on glass slides, cover slipped, studied under a compound microscope and identified: Cestoda *Ophiotaenia perspicua* (small intestine) and Nematoda *Paracapillaria sonsinoi* (large intestine), *Terranova caballeroi* (stomach), *Contracaecum* sp. larvae (body cavity), and *Porrocaecum* sp. larvae (small intestine). Voucher specimens were deposited in the United States National Parasite Collection (USNPC), Beltsville, Maryland as: *Ophiotaenia perspicua* (USNPC 104628); *Paracapillaria sonsinoi* (USNPC 104630); *Terranova caballeroi* (USNPC 104632); *Contracaecum* sp. (USNPC 104629); *Porrocaecum* sp. (USNPC 104631).

Prevalence (number infected snakes/number examined snakes × 100) and mean infection intensity (mean number helminths per infected snake) were: *Ophiotaenia perspicua* (prevalence 92%, cestodes were intertwined and could not be counted); *Paracapillaria sonsinoi*; (prevalence 8%, mean intensity 5.7 ± 5.7 SD, range = 1–12); *Terranova caballeroi*; (prevalence 11%, mean intensity 1.3 ± 0.5 SD, range = 1–2); *Contracaecum* sp. (prevalence 13%, mean intensity 2.4 ± 3.1 SD, range = 1–8); *Porrocaecum* sp. (prevalence 5%, mean intensity 2.0 ± 1.4 SD, range = 1–3).

The ascarid nematode *T. caballeroi* was described from specimens taken from the stomach of *Cubophis cantherigerus* from Cuba (Barus and Coy Otero 1966. Poeyana 23:1–16). The life history is unknown. The definitive hosts of species of *Contracaecum* are piscivorous birds and mammals; larvae hatch in water and are ingested by invertebrate hosts; fish serve as vertebrate intermediate hosts (Anderson 2000. Nematode Parasites of Vertebrates: Their Development and Transmission, 2nd ed. Publishing, Wallingford, Oxon, U.K. 650 pp.). Species of *Porrocaecum* sp. are parasites of the intestines of birds; earthworms serve as intermediate hosts and small mammals that consume earthwotms may serve as paratenic (= transport) hosts (Anderson, *op. cit*).

Contracaecum sp. and *Porrocaecum* sp. in *N. r. werleri* are new host records. Veracruz, Mexico is a new locality record for all helminths found in *N. r. werleri*.

We thank Jeanette Areola, Daniel Covarrubias, Breann De Santiago and Brenda Molgora (Whittier College) for assistance with dissections.

***NINIA MACULATA* (Banded Coffee Snake). REPRODUCTION.** *Ninia maculata* is a diurnal species distributed from Honduras to Costa Rica from 36 to 1800 m in elevation (Savage 2002. The Amphibians and Reptiles of Costa Rica: a Herpetofauna Between Two Continents, Between Two Seas. Univ. Chicago Press, Chicago, Illinois. 934 pp.). It is considered abundant across its range and inhabits a wide variety of habitats, including urban, semi-urban, and agricultural areas. To date, there has been little data published on the reproduction of this species. Here we report some observations on the nesting and reproductive ecology of *N. maculata* in an urban habitat in the Central Valley of Costa Rica, including an extension of the nesting season and information on an unusually large clutch based on the size of the female.

On 25 September 2003 we observed a female *N. maculata* (SVL = 215 mm; tail length = 70 mm) laying eggs at 2100 h in the leaf litter under closed forest cover in a small forested area at the Instituto Nacional de Biodiversidad Park (INBio Parque), which is located within the urban area of Santa Rosa in Santo Domingo de Heredia, Costa Rica (9.97365°N, 84.09310°W, datum WGS84; elev. 1128 m). The clutch consisted of three eggs measuring 28, 29 and 30 mm by 13, 14 and 15 mm, respectively. The eggs were deposited in a small hole in the leaf litter with high moisture levels, and the hole was entirely within the leaf litter and did not reach the mineral layer of the soil. All three eggs hatched on 15 March 2004, completing an incubation period of 5 months and 20 days, with offspring measuring 76, 80 and 86 mm SVL. The incubation period has not been reported previously for this species. This observation also increases the previously reported period for egg laying; Solórzano (2004. Serpientes de Costa Rica. Instituto Nacional de Biodiversidad. Santo Domingo de Heredia, Costa Rica. 791 pp.) reported that egg laying occurs between October and March and hatching between January and June. Our observation is in agreement with year-round reproduction observed by Fitch (1970. Univ. Kansas, Mus. Nat. Hist., Misc. Publ., 52:1–247). Finally, based on previous work by Goldberg (2004. Tex. J. Sci., 56:81–84), this observation represents an unusually large clutch based on the female's body size.

We acknowledge support from the CONACYT scholarships to JFGM (255983) and to AHEG (217838). V. Obando, J. Montero and A. Herrera supported JFGM's work at INBio. We also thank J. Pacheco, A. Cepeda and S. Wyatt for their editorial input.

***OLIGODON ARNENSIS* (Common Kukri Snake). DIET.** Snakes of the genus *Oligodon* are commonly known as Kukri snakes because of their knife-shaped hind teeth which are curved like a Nepalese knife (Kukri). The interesting morphology of their teeth is very effective for cutting open eggs, upon which this these snakes commonly feed (Green et al. 2010. Asian Herptol. Res. 1:1–21). Here we report an instance of *Oligodon arnensis* preying upon a lizard, the skink *Eutropis multifasciata*. On 27 February 2011, at 2030 h, we observed an *O. arnensis* in the process of subduing an *E. multifasciatus* in the botanical garden of Robertson College (23.16237°N, 79.9700°E, datum WGS 84; elev. 414 m) Jabalpur, Madhya Pradesh, India. The snake took approximately 25 min to completely swallow the skink, after which it retreated into a burrow on an elevated site nearby. To our knowledge, this is the first record of *E. multifasciatus* in the diet of *O. arnensis*.

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

FIG. 1. *Oligodon arnensis* preying upon a skink, *Eutropis multifasciata*, in Madhya Pradesh, India.

***OXYBELIS AENEUS* (Mexican Vinesnake). DIET.** *Oxybelis aeneus* is a common colubrid snake inhabiting a variety of habitats throughout Mexico, Central America, and northern South America (Savage 2002. The Amphibians and Reptiles of Costa Rica: a Herpetofauna Between Two Continents, Between Two Seas. Univ. Chicago Press, Chicago, Illinois. 934 pp.). This species is known to consume a wide array of prey, including lizards, amphibians, arboreal mammals, small rodents, small birds and fledglings, insects, and fish (Henderson 1982, Amphibia-Reptilia 3:71–80; Hetherington 2006, Herpetol. Rev. 37:94–95). Studies indicate that lizards, particularly anoles, are important prey for *O. aeneus* (Lee 1996. Amphibians and Reptiles of the Yucatán Peninsula. Cornell Univ. Press, Ithaca, New York. 500 pp.). On 26 May 2010, at 1300 h, on Playa Ventura, Guerrero, México (16.54097°N and 98.90697°W, datum NAD27; elev. ca. 48 m), one of us (AN-A) observed an *O. aeneus* in the process of constricting an adult *Sceloporus squamosus* which later was ingested head first (CAREM 0001 photographic voucher). This observation is the first record of *S. squamosus* in the diet of *O. aeneus*.

Toluca, Estado de México, México.

***OXYRHOPUS FORMOSUS* (False Coralsnake). ELEVATION.** *Oxyrhopus formosus* is a rare and poorly studied snake with a disjunct distribution in northwestern South America and in the Atlantic rainforest (Bailey 1986. *In* Peters and Orejas-Miranda [eds.], Catalogue of Neotropical Squamata. Part I. Snakes, pp. 229–235. Bull. U.S. Natl. Mus.). According to Bailey (*op. cit.*), *O. formosus* encompasses a complex of forms. In addition, several records identified as *O. formosus* in northern South America are, in fact, *O. occipitalis*, as pointed out by Lynch (2009. Pap. Avul. Zool. 49:319–337) and MacCulloch et al. (2009. Pap. Avul. Zool. 49:487–495). This taxonomic chaos makes it difficult to define geographic distribution limits of *O. formosus* sensu stricto, including the maximum elevations inhabited by the species. The holotype of *O. formosus* was collected in Mucuri, Bahia, Brazil, in the heart of Atlantic rainforest (Bailey, *op. cit.*). In this biome, the only information on the occurrence of the species in highlands is a photographic record from the Reserva Biológica de Duas Barras at an elevation between 550 and 738 m (Tonini et al. 2010. Biota Neotrop. 10:339–351). Here, we present the first elevational records of *O. formosus* in the mountains of the Atlantic rainforest biome.

In February 2010, an *O. formosus* was killed by farmers in a cocoa plantation on the farm Alto Bela Vista (14.61°S, 39.60°W, datum WGS84), ca. 780 m elev., in the Serra da Palha, municipality of Coaraci (Bahia), Brazil. A second individual was found at night (2200 h) on the edge of a stream in a forest (14.70°S, 39.60°W) at ca. 735 m elev. in the Serra do Corcovado, municipality of Almadina (Bahia) on 18 February 2011. These sites are about 10 km apart in Southern Bahian wet forest habitat. Voucher specimens (MZUESC 8485, 9250) are deposited in the Museu de Zoologia da Universidade Estadual de Santa Cruz, Ilhéus, Bahia, Brazil.

We are grateful to Mirco Solé and John D. Willson for their contributions to the manuscript.

ANTÔNIO JORGE SUZART ARGÔLO (e-mail: ajargolo@gmail.com), **IURI RIBEIRO DIAS, JULIANA ALVES DE JESUS,** and **TADEU TEIXEIRA MEDEIROS,** Universidade Estadual de Santa Cruz – UESC, Km 16 Rodovia Ilhéus-Itabuna, CEP 45662-900, Ilhéus, Bahia, Brazil.

***PANTHEROPHIS GLOYDI* (Eastern Foxsnake). REPRODUCTION-CLUTCH SIZE.** On 1 July 2009 we captured a *P. gloydi* at Shiawassee National Wildlife Refuge in Saginaw Co., Michigan, USA, as part of a radio telemetry joint project conducted by Central Michigan University and the U.S. Fish and Wildlife Service. The snake was a large gravid female (SVL = 1550 mm; total length = 1750 mm; 1654 g). The snake was radiographed after transmitter implant surgery, revealing a clutch of 34 eggs. To our knowledge, this represents a new maximum clutch size (previous maximum = 29 eggs, mean = 14.4 eggs) and near record length (previous maximum total length = 1791 mm; Conant and Collins 1998. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Houghton Mifflin, New York. 640 pp.). Evidence of vigorous reproduction in this species is of particular conservation interest, as this species is now uncommon or rare where it was once abundant (Harding 1997. Amphibians and Reptiles of the Great Lakes Region. Univ. Michigan Press, Ann Arbor, Michigan. 378 pp.).

ALEXANDER D. McKELVY, CUNY Graduate Center and Biology Department, College of Staten Island, Staten Island, New York 10314, USA (e-mail: amckelvy@gc.cuny.edu); **KILE R. KUCHER**, Shiawassee National Wildlife Refuge and Department of Biology, Central Michigan University, Mount Pleasant, Michigan 48859, USA (e-mail: Kile_Kucher@fws.gov).

***PHILODRYAS OLFERSII*. DIET.** The colubrid snake *Philodryas olfersii* is widely distributed in South America, occurring in Brazil, Peru, Bolivia, Paraguay, Uruguay, and Argentina (Peters and Orejas-Miranda 1970. Bull. U.S. Natl. Mus. 297:1–347). The species is known to have semi-arboreal habits and inhabit forested areas. Studies have documented a variety of diet items, including small mammals, birds, and anurans (Hartmann and Marques 2005. Amphibia-Reptilia 26:25–31; Leite et al. 2009. North-West. J. Zool. 5:53–60; Vitt 1980. Pap. Avul. Zool. 34:87–98).

On 19 December 2010 we collected a female *P. olfersii* (SVL = 890 mm; tail length = 47 mm; mass = 203 g) in restinga habitat (coastal sand dune vegetation habitat of the Atlantic Rainforest domain), municipality of São João da Barra, State of Rio de Janeiro, Brazil (21.7374556°S, 41.0311306°W; datum WGS84). The snake was unresponsive, and when dissected, was found to contain the digested remains of a colubrid snake, probably *Clelia* or *Boiruna*, based on head scales, in its stomach. We also observed a large edema and a perforation at the posterior portion of the stomach and necrosis of adjacent tissues, including rib musculature (Fig. 1.). In that portion of the stomach, we found the decomposed remains of a keeled-scaled viperid snake, likely *Bothropoides neuwiedi*, *B. jararaca*, or *Bothrops jararacussu*. We suspect that the tissue necrosis may have been caused by the venom of the ingested snake, either through a bite, or release of venom into an existing wound in the stomach of the *P. olfersii*.

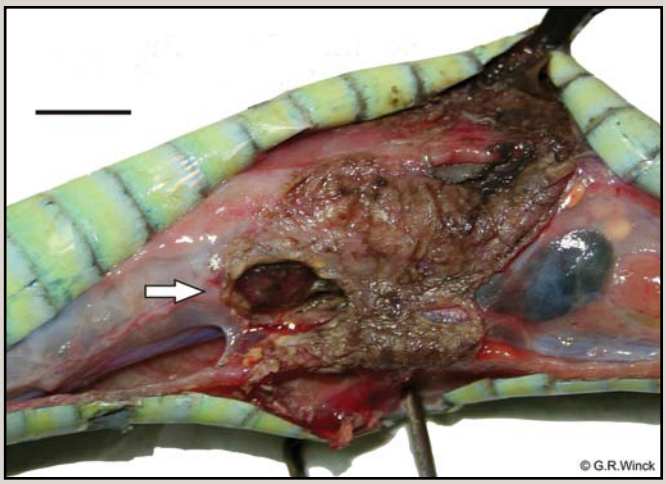

FIG. 1. Internal edema in the stomach of a *Philodryas olfersii* from the municipality of São João da Barra, state of Rio de Janeiro, Brazil. White arrow shows the perforation of the stomach, associated to the ingestion of a venomous snake.

FIG. 2. *Philodryas olfersii* found deceased with a tropidurid lizard, *Tropidurus torquatus*, protruding from its mouth. The specimen was collected at a restinga habitat, municipality of São João da Barra, state of Rio de Janeiro, Brazil.

On 21 December 2010 we collected another female *P. olfersii* (SVL = 434 mm, tail length = 200 mm, 91.1 g) in the same locality. The snake was dead with a partially ingested (head first) *Tropidurus torquatus* (SVL = 94 mm, tail length = 107 mm, 16.9 g; Fig. 2.) protruding from its mouth. Apparently, the snake failed in its attempt to ingest the lizard and was not able to regurgitate the large prey item. The inability of the snake to regurgitate may have been partially due to the lizard's scales, which are imbricated and oriented in posterior-anterior direction. Indeed, another case of a snake (*Bothropoides pradoi*) dying after attempting to ingest a large *T. torquatus* has been reported (Rocha et al. 1997. Herpetol. Rev. 28:153–154). Our observation represents an additional case of the not uncommon situation where a snake dies after being unable to regurgitate a large prey item. Voucher specimens of the snakes and the prey are housed at the Museu Nacional (MN-UFRJ), Rio de Janeiro, RJ, Brazil (the first as MNRJ 20107, and the second as MNRJ 20109).

***PHILODRYAS TRILINEATA* (Argentine Mousehole Snake). DIET.** *Philodryas trilineata* is a large and robust colubrid snake endemic to Argentina (Leynaud and Bucher 1999. Misc. Publ. Acad. Nac. Sci. Córdoba 98:1–52). The diet of this species is known to include small vertebrates such as lizards, birds, and rodents (Cei 1993. Reptiles del Noroeste, Nordeste y Este de la Argentina. Herpetofauna de Zonas Áridas y Semiáridas. Mus. Reg. Sci. Nat. Torino. Monografie IV. 945 pp.). Here we report an observation of *P. trilineata* feeding upon a novel prey species, *Upucerthia ruficauda* (Stright-billed Earthcreeper) fledglings.

On 14 December 2008, at 1411 h, in Quebrada Vallecito, Andes Mountains, Calingasta Department, San Juan Province, corresponding to pre-Andean limit of the occidental Monte Phytogeographic Region, Argentina (31.2°S, 69.6°W, datum WGS84; elev. 2543 m) we discovered an adult female *P. trilineata* (total length = 1070 mm) lying motionless beneath a shrub (*Larrea coneifolia*). As we approached, we noticed that the snake had a dark prey item in its mouth, pinned to the ground. The prey item was found to be a fledgling *U. ruficauda*. Dissection of the snake revealed another intact *U. ruficauda* fledgling in the stomach. Together, they two prey totaled 50% of the snake's mass.

The snake and prey were deposited in the Colección Herpetológica de la Universidad Nacional de San Juan (CH-UNSJ 3212)

***PITUOPHIS CATENIFER* (Gophersnake). DIET.** The feeding ecology of *Pituophis catenifer* is one of the best known of any snake species (Rodríguez-Robles 2002. Biol. J. Linn. Soc. 2002:165–183). While 213 (18%) of the more than 2600 specimens reviewed by Rodríguez-Robles (2002, *op. cit.*) contained birds or their eggs, only two contained the remains of owls or their eggs (Imler 1945. J. Wildl. Manage. 9:265–273, Short-eared Owl, *Asio flammeus*; 2 nestlings, Nebraska; McCallum et al. 1995. Wilson Bull. 107:530–537; Flammulated Owl, *Otus flammeolus* eggs, New Mexico).

On 25 May 2005, during routine nest burrow monitoring on Kirtland Air Force Base (KAFB), Bernalillo Co., New Mexico, USA, KCM and OCC discovered and photographed a dead *P. catenifer* (Fig. 1) lying approximately 15 m from an active burrow that was being utilized by a Burrowing Owl (*Athene cunicularia*) to incubate eggs that were expected to hatch around 31 May. The cause of death of the *P. catenifer* was not determined, although it contained an obvious large food bolus. After dissection, the bolus was identified as an adult Burrowing Owl which had been banded during an ongoing study of Burrowing Owls on KAFB.

During studies of Burrowing Owls on KAFB, it was suspected that adults, juveniles, or eggs had been predated by snakes. There were burrows where young chicks were observed one evening, but were missing the following morning with no signs of digging, tracks, or other mammal activity around the burrow, and also no owl feathers or carcass. To our knowledge this is the first verified report of a Burrowing Owl being preyed upon by *P. catenifer*.

PHOTO BY OCTAVO AND KIRSTEN CRUZ

FIG. 1. Dead *Pituophis catenifer* found near an occupied Burrowing Owl (*Athene cunicularia*) nest burrow, Kirtland Air Force Base, Bernalillo County, New Mexico, USA. Dissection revealed that it had consumed an adult Burrowing Owl.

***STORERIA OCCIPITOMACULATA* (Red-bellied Snake). BEHAVIOR AND REPRODUCTION.** On 7 Sep 2006, at ca. 1530 h, we observed a cluster of four adult *Storeria occipitomaculata* wrapped around a branch about 1 m off the ground in a young Sourwood (*Oxydendrum arboreum)* tree. The area was located below the main sandstone cliff-line in a small ravine in southeastern Powell Co., Kentucky, USA, a rugged area with massive sandstone cliff-lines and extensive limestone outcrops. The snakes were in such a tight mass that we could initially only see two heads but two of them dropped to the ground in response to being disturbed by our group. The remaining pair moved down the tree and escaped. Since the four snakes were all of one species and were of adult size, and the time of observation falls within the known breeding period, it is likely that this was a mating aggregation. Although individual *S. occipitomaculata* have been observed in low vegetation (Barbour 1971. Amphibians and Reptiles of Kentucky. Univ. Press Kentucky, Lexington. 334 pp.; Green and Pauley 1987. Amphibians and Reptiles in West Virginia, Univ. Pittsburgh Press, Pittsburgh. 241 pp.). Our observation of aggregative behavior in these snakes is unique in that the site was open and arboreal rather than in burrows or under objects. This observation also confirms that this species mates in late summer. Previous reports indicate that mating occurs in spring and possibly in late summer and fall (Barbour, *op. cit.*; Martof et al 1980. Amphibians and Reptiles of the Carolinas and Virginia, Univ. North Carolina Press, Chapel Hill. 264 pp.; Green and Pauley, *op. cit.*; Willson and Dorcas 2004. Southeast. Nat. 3:1–12).

***TANTILLA ARMILLATA* (Black-necked Crowned Snake). REPRODUCTION.** Much remains to be learned about the natural history of Central American snakes, particularly among the various small leaf-litter taxa. Snakes of the genus *Tantilla* are rare to common components of the leaf litter guild. Savage (2002. The Amphibians and Reptiles of Costa Rica: a Herpetofauna Between Two Continents, Between Two Seas. Univ. Chicago Press, Chicago, Illinois. 934 pp.) makes no mention of any aspect of the reproductive biology of *T. armillata* and Solorzáno (2004. Snakes of Costa Rica: Distribution, Taxonomy, and Natural History. Instituto Nacional de Biodiversidad, Santo Domingo de Heredia, Costa Rica. 791 pp.) notes only that this snake is oviparious, but that nothing is known of the reproductive cycle.

On 11 August 2010, at ca. 1130 h, a female *T. armillata* (SVL = 24.5 cm; US National Museum Field Series 254029) was collected from under a small wooden slab in cut-over forest on a hillside adjacent to La Barrigón Elementary School, 4 km N of El Copé, Coclé Province, Republic of Panama (8.6424111°N, 80.5899556°W, datum WGS84). When captured, it was noted that the snake had two eggs clearly visible through the body wall. When dissected, the eggs measured 21.39 mm × 5.28 mm and 21.04 mm × 6.29 mm. To our knowledge this is the first record of reproduction in this taxon. Pending a review of the taxonomy of the *T. melanocephala* group in Panama, we follow Savage (*op. cit.*) in the use of the name *Tantilla armillata*.

We thank K. Knight and M. Pérez for assistance in the field and La MICA Biological Station for logistical support.

JAMES L. KNIGHT, Savannah River Ecology Laboratory, PO Drawer E, Aiken, South Carolina 29801, USA and The South Carolina State Museum, 301 Gervais Street, Columbia, South Carolina 29202, USA (e-mail: jim.knight@scmuseum.org); **JULIE M. RAY**, La MICA Biological Station, El Copé de La Pintada, Coclé Province, Republic of Panama (e-mail: julie.ray@lamica.org); **KYLE BAUMGARTNER**, Department of Biological Sciences, Eastern Illinois University, Charleston, Illinois 61920, USA (e-mail: kabaumgartner@eiu.edu).

***TANTILLA RETICULATA* (Lined Crowned Snake). DIET.** Although members of the colubrid genus *Tantilla* often are referred to as "centipede snakes," the use of this food source has been confirmed for relatively few of the 60 species currently recognized (Canseco-Márquez et al. 2007. J. Herpetol. 41:220–224), especially the numerous tropical species. *Tantilla reticulata* is found at low to moderate elevations (near sea level to 1430 m) of the Atlantic versant, from southeastern Nicaragua to Panama and both the Atlantic and Pacific versants of northwestern Colombia (Wilson 1985. Cat. Am. Amphib. Rept. 370.1; Solórzano 2004. Serpientes de Costa Rica/Snakes of Costa Rica. INBio, Santo Domingo de Heredia. 791 pp.). To our knowledge, information on the diet of this snake is unavailable, except for the presumption that it feeds on centipedes (Guyer and Donnelly 2005. Amphibians and Reptiles of La Selva, Costa Rica, and the Caribbean Slope. Univ. California Press, Berkeley. 299 pp.). Here we document the consumption of an adult centipede (*Scolopocryptops* sp.) by an adult *T. reticulata* (Fig. 1.). This interaction was observed in primary rainforest on Cerro Frío, Yorkín, Prov. Bocas del Toro, Panama (9.43730°N, 82.84164°W, datum WGS 84; elev. 850 m), on 25 October 2008, at 0840 h. The two animals were found in a crack in a fallen log. The snake and the centipede are deposited in the Museo de Vertebrados de la Universidad de Panamá (MUVP 1988).

We thank Angel Solís, who took the photographs during the Expedición de Proyecto Herramientas Básicas para el Manejo del Parque Internacional Lam Amistad: Costa Rica-Panamá, financed by Iniciativa Darwin del Reino Unido. We also thank Eduardo Boza for providing the collecting information on the specimen.

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

FIG. 1. *Tantilla reticulata* found consuming a large centipede (*Scolopocryptops* sp.) at Cerro Frío, Yorkín, Prov. Bocas del Toro, Panama.

***THAMNOPHIS ELEGANS* (Terrestrial Gartersnake). DEFENSIVE BEHAVIOR.** Anti-predatory behavior of gartersnakes (*Thamnophis* spp.) has received considerable attention with respect to behavioral variation associated with either age, temperature or hormonal status of an individual under attack (e.g., Langkilde et al. 2004. Ethology 110:937–947). However, field observations under natural conditions are lacking. Here, we report variation in the anti-predatory behavior of a single *T. elegans*, exposed to mock predation by humans and dogs.

At 1000 h on a sunny day (air temp = 21°C) we captured a *T. elegans* (unsexed; ca. 700 mm total length) near the margin of a pool in an open meadow surrounded by Petran Montane Forest

FIG. 1. Dog approaching *Thamnophis elegans* from the front. Note the elevated tail of the snake.

(34.29931°N; 110.88642°W; datum NAD27; elev. 2300 m) in Coconino Co., central Arizona, USA. The snake was first captured at the pool's edge and was moved ca 10 m away to obtain photographs. As we photographed the snake, it consistently moved in the opposite direction from any person that walked toward the snake. With each approach, it reversed direction, and continued its evasive movements in the opposite direction from the nearest individual. After three minutes of these interactions, we allowed a leashed dog (Cardigan Corgi; Fig. 1) to approach the snake. Though the dog slowly approached the snake from the rear, the snake immediately ceased its forward motion and lifted its tail while simultaneously exuding cloacal contents and musk over the posterior portion of its body. The dog cautiously approached, but appeared irritated by the scent or lack of movement. The snake remained motionless for ca. 30 sec while the dog remained between ca. 30 cm to the rear of the snake. At no time did the snake re-orient to face the dog.

When the dog was removed and a person approached the snake from the rear, it again moved forward, resuming its previous pattern of escape behavior. When the dog was allowed to approach the snake a second time, from in front of the snake, it again stopped moving, elevated its tail and began exuding cloacal contents (Fig. 1). The snake remained motionless, except for tail movement, until the dog was removed, but resumed its straight-line flight behavior when approached by a person a third time. Thus, the snake's response to the approach of a human was flight, whereas it ceased movement and exuded musk and cloacal contents in response to the approach of a dog. It is unclear what proximate cues might play a role in the differential anti-predatory behavior we observed, and which natural predators may have prompted evolution of such behaviors, but our observations add to a growing list of species-specific defensive behavior exhibited by squamates when approached by potential predators. Gibbons and Gibbons (2009. Herpetol. Rev. 40:440) noted differential defensive behavior by *Coluber constrictor* in response to approaches by cats and humans, respectively, and Sherbrooke (pers. comm., 2011) has noted a number of predator-specific defensive behaviors of horned lizards (*Phrynosoma* spp.) in response to attacks by a variety of predators (carnivores, squamates).

Special thanks to Elizabeth Sullivan and Darci, the cautious dog predator.

BRIAN K. SULLIVAN and **KEITH O. SULLIVAN**, Division of Math and Natural Sciences, Arizona State University, PO Box 37100, Phoenix, Arizona 85069, USA (e-mail: bsullivan@asu.edu).

***THAMNOPHIS SIRTALIS SIRTALIS* (Eastern Gartersnake). COLORATION.** Unique color variations such as amelanism and leucism are not unusual in *T. s. sirtalis* and have been documented multiple times (Cook 1986. Herpetol. Rev. 17:23–24; Shively and Mitchell 1994. Herpetol. Rev. 25:30). *Thamnophis s. parietalis* and *T. elegans vagrans* have shown other color variations including axanthism and melanism (Mason et al. 1991. Herpetol. Rev. 22:61; Peterson and Fabian 1984. Herpetol. Rev. 15:113). Melanistic *T. s. sirtalis* have also been well documented in the Lake Eerie area (Conant and Collins 1998. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Houghton Mifflin, New York. 640 pp.). *T. s. similis* in northern Florida exhibits a blue coloration, but this is considered normal coloration and not axanthism (Conant and Collins, *op. cit.*). Axanthic individuals, however, have not been documented in *T. s. sirtalis*.

FIG. 1. An axanthic female *T. s. sirtalis* found at Table Rock State Park, Pickens Co., South Carolina.

An axanthic adult female *T. s. sirtalis* (SVL = 69 cm, 245 g) was captured on 25 May 2010 at Table Rock State Park, Pickens Co., South Carolina, USA (Fig. 1). The snake was dark gray and black with blue dorsal and lateral stripes instead of the usual yellow. Its ventral scales were also light blue in color. The snake was gravid at the time of capture and on 22 July 2010 gave birth to 31 live and 1 stillborn normal colored neonates. She later died in captivity and has been added to the Campbell Museum of Natural History at Clemson University.

MOHR**, Clemson University, Department of Forestry and Natural Resources, 261 Lehotsky Hall, Clemson, South Carolina 29634, USA (e-mail: jmohr@g.clemson.edu).

***UROTHECA EURYZONA* (Halloween Snake). REPRODUCTION.** *Urotheca euryzona* is an uncommon fossorial coral snake mimic distributed within humid forests of lowland and premontane Latin America, from northern Nicaragua south to Ecuador. On 10 March 2011, at 2345 h, we collected a gravid female *U. euryzona* (SVL = 414 mm; tail length = 222 mm, 22.2 g) moving on the ground in a section of *Manicaria* swamp forest at Caño Palma Biological Station, 8 km N of Tortuguero National Park, Limón Province, Costa Rica. One day later the snake died and was dissected, revealing five eggs. The eggs averaged 20.82 mm in length, 9.18 mm in width, and 1.10 g in mass. *Urotheca euryzona* was previously presumed to be oviparous based on the knowledge of oviparity in *U. elapoides* (Greene 1969. J. Herpetol. 3:27–31). Thus, this represents the first published account of oviparity and clutch size for *U. euryzona*. We deposited the specimen along with the eggs in the herpetological collections of the Universidad de Costa Rica. We thank the Ministerio del Ambiente y Energía Sistema Nacional de Áreas de Conservación for granting us research permits.

Many books have recently been published on the herpetofauna of Southeast Asia, but this is not just yet another of them. This new opus, a *chef-d'oeuvre* as we are tempted to say, is extremely informative and accurate, amazingly illustrated, and summarizes an impressive amount of knowledge and experience accumulated by the author on the subject treated. With its excellent glossy paper and high binding quality, it sets new, very high standards for herpetological books on the region. The author is already well known for his work on herpetological subjects in both the Old and the New Worlds and for his large number of mostly taxonomic publications on the reptiles of Peninsular Malaysia, including a recent guide on the reptiles and amphibians of the Seribuat Archipelago (Grismer 2011), and the (co-)description of 32 of the 124 Peninsular Malaysian native lizard species—i.e., more than a third!—, among them 14 of the 19 local *Cnemaspis* spp., and 8 of the 16 *Cyrtodactylus* spp.

The main sections of the book are the brief introduction (pp. 14–15), an abundantly illustrated presentation of the physical and natural environments and the climate found in the area covered by the book (pp. 17–80), a general presentation of the local herpetofauna with a history of the herpetological research on the area (pp. 81–96), the species accounts (pp. 97–703) which form the principal part of the book, including identification keys to families, genera, and species, a brief section on two introduced exotic lizard species (the iguanid *Iguana iguana* and the agamid *Physignathus cocincinus*) (p. 704), another brief section on conservation (pp. 705–707), and the bibliographic references (pp. 708–728).

With not a single exception, photographic illustrations in the book are absolutely astonishing. Among the 530 figures in the book, all in color, one is a map of Southeast Asia, two others are maps of Peninsular Malaysia, 96 show habitats (sometimes featuring a snake or an amphibian as well), and all others are lizard photographs, including lizards in their natural habitat and detailed views of body parts (such as heads with extended dewlaps or expanded wings of *Draco* spp.). Each photograph is accompanied by detailed locality data, which adds a lot of information. Actually a few photographs lack locality data (in particular, the *Gekko smithii* on pp. 82–83 was photographed on Pulau Perhentian Besar, Terengganu; the *Cyrtodactylus consobrinus* on p. 290 was in Hutan Lipur Sekayu, Terengganu; the *Eutropis multifasciata* p. 544 was in Bukit Larut, Perak, and the *Varanus salvator* on p. 683 was in Kuala Perlis, Perlis; L. L. Grismer, pers. comm.). Photos of Malaysian lizards were taken by the author in virtually all kinds of environments, from mangroves and highland cloud forests to karst caves, restaurants, and even massage parlors. One of the most extraordinary photographs in the book, on page 101, used to illustrate the introduction to Agamidae, shows a *Gonocephalus robinsonii* in its biotope. We asked Lee Grismer how this remarkable shot was taken: "The wide angle shot took several days to set up. I thought about it for a week before I shot it and I had very specific ideas and images in my head of what I wanted. I wanted a flashy upland endemic known only from a cloud forest and the shot to 'feel' cold and wet. I scouted out a place in Cameron Highlands to shoot the lizard and stayed throughout the day to determine at what time the best light would occur and hopefully get an idea of when the fog would arrive. Then I went to an area to where *Gonocephalus robinsonii* are the most attractive. I caught the lizard and brought it back to the site and set it on the log and got my gear ready. Just as I began shooting, the clouds began to roll in as you can see in the top of the photo" (L. L. Grismer, pers. comm.).

Each species account includes the scientific name of the species and its author(s), a common Malaysian name, a reference to the original description of the species with the type locality, a diagnosis, a morphological description, a coloration description, a distribution section, a natural history section, and a list of the examined museum material with collection numbers and localities. In some species, when appropriate, there is an additional section

on geographic variation. In those cases where the species is variable or suspected to be a species complex, the variation is often well illustrated in the several photographs provided, and several potentially undescribed species are illustrated (like the lowland form of *Cnemaspis mcguirei* shown on figures 287–288, which actually represents a distinct, undescribed species — L.L. Grismer pers. comm., as well as several atypically colored *Cyrtodactylus pulchellus*). Each species account is accompanied by a specific dot map, with a detailed caption listing the mapped localities (these maps are not counted among the 530 figures mentioned above). Maps are not provided for only four species: *Hemidactylus frenatus* and *Eutropis multifasciata*, because they are ubiquitous, and the two introduced alien species. About 90% of the photographs were taken by the author himself. Only nine species are not illustrated (*Pseudocalotes dringi*, *Cnemaspis argus*, *Cyrtodactylus stresemanni*, *Lygosoma bampfyldei*, *Sphenomorphus anomalopus*, *S. cophias*, *S. langkawiensis*, *S. malayanus*, and *S. sibuensis*), and just a few species were illustrated only by photographs taken out of Peninsular Malaysia (*Hemidactylus garnotii*, from Myanmar; *Eutropis novemcarinata* from Myanmar; *Lygosoma albopunctatum*, from India; *Lygosoma herberti*, from Thailand; *Sphenomorphus maculatus*, from Cambodia; and *S. stellatus*, from Cambodia and Vietnam). Such a huge proportion of photos taken of individuals native to the area covered by the book is absolutely remarkable. Too many books are illustrated by photos of individuals from populations outside the area covered, and that sometimes later turn out to belong to distinct taxa.

Detailed morphological data on Malaysian lizards were lacking for many species, and dispersed in many journal articles, often old and difficult to find. This new book offers a very complete and homogeneous description of each species, in a level of detail that has not been achieved in any synthetic work on Southeast Asian lizards since Taylor's (1963) opus on Thai lizards. These detailed morphological descriptions make the book an extremely useful tool for identification and for the future work of taxonomists.

The natural history section is based on very thorough field notes taken for 15 years and retrieved from taxonomic indices the author put in his notebooks at the end of each year, a method that was already successfully adopted for the author's book on Baja California (2002). It is by reading these field notes that one fully realizes how much field work actually entered into this book: many remote localities were visited at numerous occasions over a number of years and at different seasons, which allowed, among other useful information, a better understanding of the reproductive cycles of each species. Lee Grismer's *in situ* observations represent a really large proportion of what is presently known on the natural history of the local lizards. These natural history accounts testify to the quasi-obsessional dedication of the author to the improvement of our knowledge on each species. Another sign of this extreme dedication is the large number of Malaysian and American students and researchers Lee Grismer has trained and is still training on Malaysian herpetology through courses and group field trips, as notably reflected by the multi-authorships of many papers listed in the literature section.

The literature cited section includes 480 pertinent references, the most recent of which date from early 2011 (indeed on page 99 it is stated that the acquisition of data for the book terminated on 3 April 2011, a very useful bit of information that we would encourage all book authors to provide).

Negative points about this remarkable book are few, and to find most of them required a very thorough examination of the book. The introduction gives a list of the species with scientific and common names, but the latter are not always those used in the main text of the book. We regret the absence of an index in the book. More importantly, we feel there should be an introductory chapter on scale morphology and morphological characters used in identification keys. The keys are very well conceived, but are usable only by persons who already have a very good knowledge of lizard meristic characters. Drawings showing the various scale types, and a brief definition of each type, would have allowed more people to use the keys without needing recourse to other books describing and illustrating these characters. The key to *Draco* spp. (p. 158) largely uses the number of ribs supporting the patagium, but the variation in rib numbers in the key does not reflect the whole variation as indicated in the species accounts (see accounts for *D. formosus*, *D. sumatranus*, and *D. taeniopterus*), which might lead to some misidentifications. The key to scincid genera (p. 545) misses entries to the genera *Dasia* and *Eutropis*. The key to *Sphenomorphus* spp. (couplet 7) states that *S. langkawiensis* has 60–62 paravertebral 'scales' (actually 'scale rows'), while the species account indicates it has 60–72; this mistake has some consequences for the use of the key. In couplet 11 of the same key, there is an alternative between six and five supraoculars, but it does not take into account the variation within *S. scotophilus* (as given in the species account), which also makes the key to *Sphenomorphus* spp. a bit delicate to use. The type locality for *Lygosoma herberti* was copied and pasted from that of the former species account (*L. bowringii*: Hongkong), but is actually 'Nakhon Si Thammarat Mts., peninsular Thailand' (Taylor 1963). As the author states, the book does not intend to provide a detailed taxonomic history for each species; however, for a number of recently described species, natural history data, summarized in the species accounts' natural history sections, were published before their description, and it would have been useful to know under which name they had then been referred to. A number of references cited in the main text are missing in the literature cited section, and in the latter several references are not in alphabetical order. There are some typographic errors in the book, but these certainly do not occur with a frequency that would distract from the reading and consultation of the book. These few negative points are by no means significant in view of the extremely high general quality of the book.

Lee Grismer has to be congratulated to have restricted himself to a limited and manageable taxonomic group over a limited geographical area, and to have provided detailed and comprehensive information about it, as well as identification keys including all species treated and photographs illustrating nearly all of them. There is indeed a dangerous tendency, maybe motivated by commercial reasons imposed by publishers, for guides to cover too many species over a too large geographical area. This tendency is well examplified by a recent "field guide" that treats about 1000 reptile species and subspecies from eight Southeast Asian countries (Das 2010), including Malaysia and Singapore. This represents so many taxa and so much information to deal with that in the end, to fit in a single book, descriptions had to be extremely brief and not sufficiently diagnostic. Further, no keys were provided, more than a third of the lizards were not illustrated, and much information is missing or erroneous, rendering the guide very superficial and nearly impossible to use in the field for identification purposes (Pauwels and David 2011). Accounts on Malaysian lizards contained so many errors that in the opus discussed here, Grismer had to mention these mistakes in not less than 48 instances throughout the book.

Lee Grismer's latest book is absolutely exceptional by universal standards, and it is without any hesitation that we strongly recommend it to all naturalists, herpetologists, teachers, and conservationists who want to know more about Malaysian lizards and Peninsular Malaysia. The author is currently working on the description of more than 15 new Malaysian lizard species (Gekkonidae and Scincidae), that will be integrated into a next edition of the book; with Malaysian colleagues he is finishing up a book on Malaysian snakes, and he will as well participate in a book on Malaysian amphibians that should appear next year—all books will be of the same style as the one treated here (Grismer, pers. comm., Dec. 2011). Needless to say, we are waiting impatiently.

Herpetologists know that amphibians and reptiles are endlessly engaging of the mind and spirit, and deserving of our efforts to protect them and their habitats. We do require people, however, who can transition information from herpetological journals to popular outlets. We especially need those who can reach out to children, because as the author notes in her dedication to this book, children "hold the future of amphibians and reptiles in their hands."

According to information posted on Amazon.com, Marty Crump's latest book is intended for middle-school children and older. It is a revision of the first edition (2002), which became, according to the publisher's website, "the 'Outstanding Trade Book for Students, K-12' in 2004 and 'Selector's Choice,' an award given jointly by the National Science Teachers Association and the Children's Book Council."

Dr. Crump is well-known to readers of this journal for her work in tropical herpetology and behavioral ecology, which led her to author such books as *In Search of the Golden Frog* (2000), *Headless Males Make Great Lovers: And Other Unusual Natural Histories* (2007), *Sexy Orchids Make Lousy Lovers: & Other Unusual Relationships* (2009), and *Extinction in Our Times: Global Amphibian Decline* (2009, coauthored with James P. Collins). The book under review here is the second of her children's books; the other is the recently-published *Mysteries of the Komodo Dragon: The Biggest, Deadliest Lizard Gives Up Its Secrets* (2010). She is also the coauthor of one of the herpetology textbooks, now in its fourth edition (2009).

Since this book is pitched at children in grades 6–8, I ran the first paragraph of the first chapter through a test for readability scores, which provided a mean score of 7.7 grade level for five measures, which is appropriate. The book contains 17 chapters, which have an average length of 13.1 pages. This seems like a comfortable read for the intended 12–14-year-olds, especially as the chapters often are divided into sections and provided with numerous illustrations.

I found two features of the book's chapters especially inviting. One is that the illustrations, both black-and-white (135 of them) and color (eight multi-photo plates), have legends that provide the reader with some interesting information about the creature pictured. For example, the legend for figure 7 on page 9 of the first chapter reads: "Komodo dragons, the largest lizards in the world, get their food in three major ways. They ambush active prey, attack sleeping animals, and eat dead animals such as these fish washed up onto the beach." The photograph, naturally, shows one of these varanids consuming some dead fish.

Among the color photographs is one that is truly "suitable for framing." It shows Dr. Brady Barr hefting a 4-foot 9-inch *Andrias japonicus*. The question posed by the author is how he can manage to hold onto such a slippery creature. Although Brady is smiling (well, maybe grimacing), he is probably hissing "Quick, take the damn photo!" This photo also appears on the AmphibiaWeb site and must be seen to be believed. The information provided there indicates that the animal (the salamander, not Brady) weighed 86 pounds (39 kg).

Another color photo, of the Titicaca Water Frog (*Telmatobius culeus*), taken by Danté Fenolio, is rather eerie. Crump says, "What a face!" I agree. It is a good choice to place in this book, since this species is judged Critically Endangered by the IUCN, having undergone an 80% population decline in the last 15 years (amphibiaweb.org).

The other feature I found inviting is that words that might prove difficult for middle-schoolers are italicized, indicating they are defined in the four-page glossary. Nonetheless, an indication of their meaning often appears in the text, which helps the reading ease and promotes vocabulary expansion.

Dr. Crump's book also features three appendices. Appendix I lists additional resources (books and websites) on amphibians and reptiles, and their conservation (six pages). Appendix II provides names and addresses for 17 conservation organizations, ranging from the big, broad-scale groups like Conservation

International, World Wildlife Fund, and Worldwatch to groups with a narrower focus, such as Save the Frogs. Appendix III offers some "amphibian and reptile place names," such as Frog Suck, Wyoming, Toad Suck, Arkansas, and Lizard Lick, North Carolina, with an invitation for the reader to find more (the three I mention would be hard to beat). Appendix IV lists the photographic credits. The book concludes with a page and a half listing of the "main sources consulted," which are, as the author notes, "in addition to more than 100 scientific papers." An eight-page-plus index also is included, in which the references to illustrations are in boldface type.

The first six chapters are concerned with the natural history of amphibians and reptiles and the remaining 11 with their conservation. The initial chapter is entitled "Too Weird to Be True?" and is intended to pull the reader into the book. It deals with the appearance, defense mechanisms, parental care, and feeding of amphibians and reptiles and uses several unusual creatures as examples. The author notes that as "interesting as these isolated tidbits of information are, they really don't tell us much about reptiles and amphibians," so the next four chapters introduce more typical species to the reader. The first of these chapters answers the question "What are Amphibians and Reptiles?" by discussing their similarities and differences. Also, a two-and-a-half-page box introduces scientific classification and another provides four examples by using the seven standard taxonomic levels. Nevertheless, scientific names generally are avoided, although they could have been included in another appendix. The three chapters that follow, one of which deals with amphibians and the other two with reptiles, provide more details. As expected, each of these chapters is subdivided along ordinal lines, with discussions that summarize general information in a pleasant but information-packed narrative.

Chapter 6 describes the key roles amphibians and reptiles play in their ecosystems and sets the stage for the principal purpose of the book—to promote conservation. In doing so, Dr. Crump emphasizes the "conveyor-belt" role these animals play in "transfer[ing] energy from invertebrates to *endothermic* predators higher up the *food chain*." Thus, she provides a rationale for conserving amphibians and reptiles in their natural habitats by asking the question, "What would happen if Earth lost large numbers of amphibians and reptiles?" This central question is coupled with another, "How much longer will amphibians and reptiles be around to serve as critical components of ecosystems?," which provides the focus for the remainder of the book.

So, significant emphasis is placed on conservation, inasmuch as more than half of the book (131 of 249 pages) is devoted to this subject (indeed, this is the reason I was interested in reviewing this book). The author's examination of conservation issues begins with Chapter 7, entitled "Disappearing Acts." As its name suggests, this chapter deals with examples of decline and disappearance, the IUCN conservation status categories, numbers and percentages of amphibians and reptiles under threat, the six major causes of amphibian and reptile declines, and the features that render certain of these creatures more prone to population decline.

Chapter 8, entitled "Why Should We Care?" presents arguments explaining why amphibians and reptiles should be of concern to humans. Crump notes that we should care because we are responsible for most of the declines, we are still learning about these organisms, we put them to important uses, we recognize their importance in both aquatic and terrestrial ecosystems, and we acknowledge that "every living species has a right to exist."

The next two chapters explore direct and indirect reasons why amphibians and reptiles are undergoing decline. Chapter 9 considers the direct impacts, including the use of skins for leather and whole animals and parts as souvenirs, the use of flesh as food, the use of live creatures as pets, the use of body parts in folk remedies and modern medicine, and the use of living and preserved animals in research and teaching. Chapter 10 examines the indirect impacts of habitat modification and destruction, the introduction of exotic species, and environmental pollution.

Chapter 11 is entitled "Who Turned Up the Heat?" and obviously discusses global warming. The author indicates that humans have created the problem by burning fossil fuels, and disabled the fundamental solution by cutting down trees and plants, the carbon dioxide absorbers. She also notes that many amphibians and reptiles, including their eggs, might not be able to adapt to the warmer, drier conditions, as well as the predicted increase in UV levels.

The major environmental problem facing amphibians is discussed in Chapter 12, entitled "Attack of the Killer Fungus!" Logically, Dr. Crump begins the story of *Bd* with her personal story of watching *Incilius periglenes* disappear from the elfin forests at the Monteverde Cloud Forest Reserve in northern Costa Rica during the unseasonably warm and dry 1986–1987 period. Jay Savage had described this extraordinary toad only two decades earlier; since then, this anuran has become the "poster child" for amphibian conservation. Although the disappearance of *I. periglenes* has not been linked to *Bd* infection, this disease certainly has been demonstrated to be the causal agent in the decline of other amphibian populations on all continents where they occur. The author uses the El Valle, Panama, example of the "heroic airlift" that removed individuals of 35 species to sanctuary in Atlanta, Georgia, to ask a number of ethical questions about which species should receive our attention and for how long, especially since conservation dollars always are limited. Does it make sense to maintain certain species in captivity in the unconfirmed hope that their natural homes eventually might be able to support them in the indeterminate future? These kinds of questions can be used to set up debates in middle-school classes to teach students how to construct defensible arguments.

The remaining five chapters examine solutions for amphibian and reptile conservation, beginning with a chapter on human attitudes toward these creatures, entitled "Good or Bad? Love or Hate?" The author notes that people will "protect amphibians and reptiles only if they think these animals are worthy of protection." However, according to the author, only a nickel of every conservation dollar is spent on these animals. Then, the reader is regaled with stories of these organisms as symbols of both good and evil, depending on the nature of the superstitions and legends involved. She concludes the chapter by emphasizing the importance of knowing what people think about these creatures, as a prelude to changing negative attitudes that will increase our appreciation and desire to protect them.

Chapter 14 asks the question "We Can Live Together, Can't We?" The main point of this chapter is evident in the concept of living together and not apart. That is, conservation biologists must find ways to provide living spaces for amphibians and reptiles in a world that, as I write this sentence on Halloween, 2011, now supports a human population of seven billion. The seventh billion was added in just 12 years, the same length of time it took for the sixth billion to accrue. Dr. Crump emphasizes not only an obvious solution, preservation of land, but also ways in which we can change how we use the environment to promote amphibian

and reptile survival, such as building under-road tunnels (I am writing this review in Gainesville, Florida, where just south of town such structures have been installed in the road across the famed Payne's Prairie), digging ponds to facilitate amphibian breeding, and using shrimp nets equipped with turtle excluder devices.

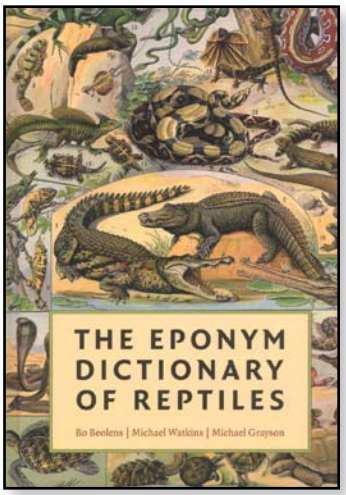
The final three chapters deal with ways to help conserve amphibians and reptiles. Chapter 15 is concerned with "Research and Education." For herpetologists, it is self-evident that "We need more research to understand how we can best protect amphibians and reptiles." Clearly, we know much less about their lives than we have discovered to date, especially as new species continue to be discovered. As new taxa are named, the number and percentage of threatened forms will likely increase, and each new taxon will represent a new biology to explore. Since most species remain poorly-known, biologists are facing an enormous task. So, basic research is essential, as long as the right questions are being asked. Environmental education programs are the link between scientists and the public, and the author notes that such programs can be coupled with tourism to become ecotourism or provide opportunities for non-scientists to participate in scientific research. She also points out the importance of private individuals (read "children") educating themselves to become agents of change to benefit conservation.

Chapter 16, "What Else Can Be Done?," treats of other ways to protect amphibians and reptiles, such as through laws like the Endangered Species Act and the CITES treaty, which work when properly enforced. In addition, populations can be reestablished in their natural habitat, animals can be captive bred for skins, food, and pets, wild populations can be harvested more wisely, and alternatives to classroom specimen dissections can be used, like videotapes, CD-ROMs, and computer-based virtual dissections.

The last chapter is oriented toward the reader and asks, "What Can YOU Do to Help?" Actually, the discussion is divided among things for the reader to do—and not to do. The things not to do are somewhat limited, but the ones to do are more extensive, such as educating oneself about these animals, volunteering time to individuals and organizations, sharing information with others, supporting conservations organizations, being a responsible pet owner, and improving one's backyard to serve as habitat for amphibians and reptiles. The last paragraph of the book presents a simple, but powerful message—"You and I together can make a difference. Please help."

Marty Crump has done herpetologists a tremendous favor in creating this book directed toward middle-schoolers. She transferred our concerns about the fate of amphibians and reptiles expressed in our technical papers and books to the young people who can make a real difference in the years to come, in a way they can understand. She carefully crafted her book using the appropriate language level and engaging information about "our" creatures that can be read on more than one level. The text can be read straight through to provide a strong conservation message, but also can be explored more deeply by pursuing the information in the additional references and various appendices.

Although my elder grandson, at age nine, is still a bit young for this book, I think his burgeoning interest in herpetology will stand him in good stead and I plan to give him my copy. It won't be so long, anyway, before he will be ready to handle all this excellent book has to offer.



I have just a couple of suggestions for improvement, should this book go into a third edition. One is to turn the black-and-white illustrations into color. Amphibians and reptiles are colorful organisms and seeing their color patterns can increase their appeal to young readers. The other is to include ideas about appropriate projects and presentations for the target audience to make in school and other social settings.

e-mail: uetz@vcu.edu

Most reptile aficionados will recognize that *Amphiesma boulengeri* has been named after George Albert Boulenger (1858–1937) or *Plestiodon copei* after Edward Drinker Cope (1840–1897). But who was the Dugand in *Leptotyphlops dugandi* (now *Trilepida dugandi*) or the King in *Anops kingi* (now *Amphisbaena kingii*)? Such questions are answered by the *Eponym Dictionary of Reptiles*, which tracks down the people after whom species have been named. This book is welcome because the issue at stake is not that trivial. For instance, there are quite a few species epithets which appear to be named for people but which originate from place names, such as *Chironius vincenti* named after the island St. Vincent. These cases are covered too. In addition, the dictionary contains those species that have been named after people but may not be obvious, e.g., *Eurydactylodes agricolae*, named after Aaron Bauer, whose last name means "farmer" in German, which is translated to "agricola" in Latin. Finally, some reptile names which may sound like people, such as *Anolis bicaorum*, have been named after organizations, here the Bay Island Conservation Association (BICA). While such cases are also included in the dictionary, they may not have been covered comprehensively as the origin of some names remains mysterious. Many older species descriptions did not explain their etymology, so once their authors have passed away it becomes a detective's job to figure out their history. In addition to the scientific names, Beolens et al. also catalogued those common names derived from people, such as Blanford's Pipe Snake (*Cylindrophis lineatus*), even though the scientific name is of purely Greek and Latin origin. Finally, a surprising number of species (or genera) have been named after mythical characters, be they from Tolkien's Lord of the Rings (*Liolaemus tulkas*) or Burroughs' Tarzan (*Calumma tarzan*), appropriately named after its arboreal lifestyle.

The Eponym Dictionary tracks down the names of a total of 4,130 species and subspecies and is alphabetically organized by eponym, that is, usually the last name of the person (or sometimes place, organization, etc.) after which species have been named. Each entry then lists the species named after that person. Most people have only one or two species named after them, but the superstars such as Boulenger or Cope can claim dozens of species named in their honor. For each person a very short biography is provided, sometimes only a sentence ("Charles Snell donated the holotype of this snake [*Vermicella snelli*] to the Western Australian Museum") but rarely exceeding a quarter of a page, even for the most famous herpetologists. While this heterogeneity is a certain weakness of the book, it may have been a necessary compromise to keep the book's size manageable. Nevertheless, it is one of those dictionaries which you may end up reading just for fun as it is a treasure trove of anecdotes, amusing factoids, and family gossip (many herpetologists named some snake or turtle after their wives [often!], sisters, uncles, mother-in-laws, or other family members and friends). We also learn about less pleasant aspects of being a herpetologist, such as the abrupt ends of Roberto Donoso-Barros (*Liolaemus donosoi* and other species) and Benoit Mys (*Carlia mysi*) in car crashes or Johan August Wahlberg (*Colopus wahlbergii*), who was killed by an elephant, or those scientists who died, perhaps fittingly, from snake bite (e.g., Robert Mertens and Joseph Slowinski).

Besides the heterogeneity of the entries, I have only few complaints: first, the introduction and background information is limited to a mere three pages. Here the authors explain how to use the book and how they dealt with dubious names (such as those common names erected by Frank and Ramus). I would have liked to see a bit more data analysis, e.g., some statistics (where the patrons came from, when they lived, etc.) or a list of epithets that are neither Greek or Latin nor derived from people. It would have been helpful to indicate for which names more extensive biographies or obituaries are available. While some resources are cited (e.g., Adler 1989, 2007; Rieck et al. 2001), there is no information on whose biographies they contain. Furthermore, the whole bibliography is less than two pages so you have to resort to other resources to find the original descriptions of the species listed (e.g., the supplement to Uetz 2010).

Despite its shortcomings, Beolens and co-authors have produced a great book that is fun to read. Notably, they have already published similar books on birds and mammals (Beolens and Watkins 2003; Beolens et al. 2009) and reportedly have a companion volume on amphibians in press. If they live long enough to work through the 30,000 species of fish, a future eponym dictionary of vertebrates may keep saving biologists from buying *People* magazine for years to come.

Amphibians of Malawi

by Vincenzo Mercurio. 2011. Edition Chimaira, Frankfurt am Main (www.chimaira.de). 393 pp. Hardcover. 49,80 Euros (approximately US $65.00). ISBN 978-3-89973-495-9.

HENDRIK MÜLLER
Institut für Spezielle Zoologie und Evolutionsbiologie, Friedrich-Schiller-Universität Jena, Erbertstrasse 1, D-07743 Jena, Germany
e-mail: hendrik.mueller@uni-jena.de

Recent years have seen a welcome proliferation of high quality country and regional field guides to the amphibians and reptiles of various parts of Africa (e.g., Baha El Din 2006; Channing and Howell 2006; du Preez and Carruthers 2009) and a new book by Vincenzo Mercurio on the amphibians of Malawi continues this trend. Malawi is a comparatively small southern African country that is wedged in among Tanzania, Mozambique, and Zambia and extends along the southern part of the East African Rift Valley and Lake Malawi. Although Malawi has an interesting geographical position between the mountains of Southern Africa and those of the Albertine Rift and the Eastern Arc, it lacks the high number of endemic amphibian species found to the south and north. As such, Malawi has received relatively little attention and has usually been considered only peripherally in treatments of the herpetofauna of its more important southern and eastern neighbors. The only notable exception has been Margaret Stewart's (1967) seminal book *Amphibians of Malawi*—the first and only comprehensive guide to the amphibians of Malawi. With his new book, Mercurio presents a complete update of our knowledge of the amphibians of this country.

The book is based on Mercurio's Ph.D. dissertation, which explains the somewhat unconventional (for a field guide) arrangement of the different parts of the books into introduction, material and methods, results, discussion, abstract, German summary, and a bibliography. The first part comprises some 50 pages and contains more or less comprehensive introductions to the geography, geology, climate, and particularly the vegetation, with several subsections devoted to the various predominant vegetation types. Further sections are dedicated to the current state of conservation, list protected areas, and provide an overview of the history of herpetological research in Malawi as well as of studies using amphibians as biological indicators in Africa in general. The second part (Material and Methods) gives details on the survey methods used and on data analyses. Of more interest to most readers in this chapter will most likely be the detailed

descriptions of the sites visited for the study. Both introduction and material and methods are amply illustrated with a number of maps (political, geographical, hydrological, protected areas, study sites) and excellent, representative photographs of the different habitat types and study sites visited.

The bulk of the results section contains the systematic accounts, which cover 86 taxa including two possible new species and four subspecies and include keys to all genera and species. All species accounts contain a list of synonyms and list the pertinent literature, a brief diagnostic description of the species, the geographic range, the distribution in Malawi, and habitat. Every account is completed by a distribution map indicating known records from Malawi. Most species accounts further contain a section with remarks and, where applicable, a list of examined material (with museum/field numbers) and a description of the advertisement call complete with accompanying spectrograms and oscillograms. With a few exceptions, every species is illustrated by one, sometimes more, good quality photographs. In addition, some species accounts also include photographs depicting the typical habitat.

The remainder of the results contains a section describing the diversity of reproductive modes of the anurans of Malawi and another section with an analysis of species richness and community diversity. The section on reproductive diversity is largely identical to Mercurio et al. (2009) and contains descriptions of the anuran reproductive modes (following Wells 2007) found in Malawi, as well as a comprehensive table listing every species with its reproductive mode and further reproductive characters such as clutch size, egg deposition site, tadpole habitat, etc. Alas, information on whether the tadpole of a given species has been described or is unknown is missing.

The relatively short discussion mostly summarizes and synthesizes the distribution and abundance data from the results section. The main conclusion is that at the species level there is a "lack of a match between environmental degradation and amphibian diversity." As a reason for this result, the author suggests either considerable ecological plasticity of the Malawian anurans or a change in the amphibian communities in historical times due to progressive human habitat modification, a scenario which overall does not seem to be all that unlikely. As the author furthermore points out, true forest endemics or other habitat specialists are almost completely absent from the sampled species and most of them are habitat generalists, which may also account for the lack of correspondence between habitat degradation and amphibian diversity. These main results are furthermore even less surprising when considering that apparently only species with a good visibility and thus likelihood of detection were selected for the abundance analyses, whereas small ground-dwelling, aquatic, or fossorial species were excluded. Given that the resulting data set contains primarily species known to be tolerant of anthropogenic habitat modifications it is not surprising that the author arrives at his main conclusion.

Overall, as a field guide, the book seems well worth its price. Especially the detailed and well-illustrated introductory chapters and species accounts provide a lot of information; anyone planning on visiting Malawi or interested in the amphibians of the area in general will find plenty of interest here. Unfortunately a list of museum acronyms seems to be lacking. Moreover, some of the acronyms given for the examined material seem to indicate field numbers (VM – Vincenzo Mercurio?), rather than collection numbers, and I could not find any mention in the book into which museum collection these specimens will be accessioned, if they have not been already. What detracts further from the overall positive impression of the book are some entirely unnecessary errors and typos. The figure legends especially contain a disproportionately high number of errors; some examples: fig. 82 shows a specimen of *Leptopelis mossambicus* in "position of minimus traspiration" and refers to figs. 67 and 69, which supposedly illustrate the same specimen but in fact represent the distribution map and a photograph of *Arthroleptis xenodactyloides*. Figure 215 refers to a "*Hyperolius viridiflayassaevus*" instead of *Hyperolius viridiflavus*, fig. 298 to "*Ptychadena* cf. *fuscigula*" instead of *Amietia* cf. *fuscigula*, and fig. 304 to "*Afrana angolensis*" instead of *Amietia angolensis*. In Table 10, the percentages for the Chongoni sample do not add up to 100%. The records for *Phrynobatrachus perpalmatus* are indicated by giant red squares in the distribution map, instead of the small dots used in the other maps. In addition, there are a number of simple typos throughout the text (e.g., "*P. uzugwensis*," "*S. murumontanus*," "embrionic development") as well as grammatical errors. After all the work that went into this book, it is regrettable that neither the author nor the publisher seemed to have found the time for that final round of proof reading.

Snakes and Reptiles: The Scariest Cold-Blooded Creatures on Earth

by Susan Barraclough. 2008. Sandy Creek Press, 122 Fifth Ave., New York. Hardcover. 192 pp. US $25.95. ISBN 9781435107748.

WILLIAM I. LUTTERSCHMIDT
Department of Biological Sciences, Sam Houston State University
Huntsville, Texas 77320, USA
e-mail: lutterschmidt@shsu.edu

Although one may find a review of a children's book a bit out of the ordinary from typical reviews of scholarly works in herpetology, I believe this one to be no less important. I appeal to my fellow herpetologists, colleagues, and parents who frequent the children's sections of local and national

FIG. 1. Examples of the overdramatized illustrations and accounts presented in this book creating undo fear among children. Examples presented here include a woman collecting timber from a woodpile in her garden who is subsequently bitten by a coral snake (A), a man bitten by a cottonmouth while canoeing in Florida (B), and a Brazilian fisherman bleeding out in his boat after attempting primitive first-aid on the bite wounds (C). Illustrations are copyrighted by Sandy Creek Press with arrangement with Amber Books, Ltd.

bookstores with their sons and daughters. What I found and present here is most offensive to our passionate and professional efforts to create an appreciation and respect for the animals we study. We are all too familiar with how the presentation of misleading and inaccurate information creates misconceptions in herpetology and the "only good snake is a dead snake" mentality. I, as do so many of my colleagues, dedicate countless hours to educating our youth about amphibians and reptiles in an attempt to shape future citizens that are well informed and educated so that they might also share our appreciation and respect for these unique animals and their interesting natural histories. The above author, Susan Barraclough, has now touched the minds of thousands (ca. 18,000 copies sold)[1] and has single-handedly undermined our efforts to properly educate and instill an appreciation and respect for reptiles. Instead, such appreciation is replaced with undue fear, misunderstanding, and a certain propensity for wanton killing.

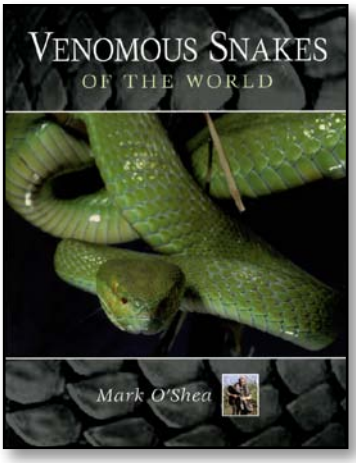
This book is targeted toward a very impressionable age group of 8 to 10 year-olds and is littered with outrageous images (e.g., Fig. 1) in an attempt to create a true sense of fear rather than wonderment. Even the quote on the inside cover "…reptiles are the real-life monsters of the modern world" and the quotes within the cottonmouth account (e.g., "As dark and sinister as its swampland habitat, this fierce hunter haunts the sluggish waters of southeastern United States" and "After the snake plunges its fangs into a victim, it hangs on until its venom starts to work") are unconscionable statements for someone who is supposedly dedicated to the education of children. The book's jacket states that "Susan Barroclough is a highly experienced author and editor specializing in children's nonfiction and reference books" and "during her career she has written and managed a wide range of teen and children's titles on science and the natural world." It seems that the author has now managed to fit a project of science fiction into her repertoire.

In addition to this "reference book" being clearly overdramatized all for the sake of creating a fear factor, it is also riddled with errors and misconceptions (Table 1). However, my objective here is not to critically review the material presented in this book, but rather to draw attention to the educational "miscue" that has now influenced thousands of impressionable children. As true science educators we understand and share a basic educational philosophy for meeting curiosity with honesty and scientific integrity, especially when touching the minds of children. This book has failed in this basic and essential educational philosophy. In my professional opinion, this publication may be a perfect example of how not to educate our youth about science and natural history. As most of my colleagues will likely concur with my assessment of this book, I assure you that this book is one that I will be keeping off my son's bookshelf.

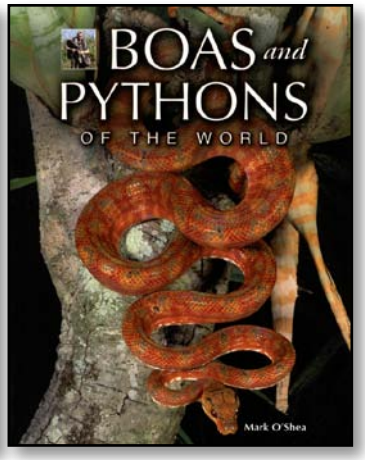
TABLE 1. Representative examples of errors and misconceptions presented in the book, *Snakes and Reptiles: The Scariest Cold-Blooded Creatures on Earth.*

Example	Error or Misconception
1	"Snakes and Reptiles" rather than "Snake and other Reptiles" (title page).
2	Perpetuation of the term "cold-blooded" rather than the use of ectothermic (title page).
3	Use of "*species*" rather than species or sp. to indicate a non-specified specific epithet of the genus (throughout book). By italicizing the word species this indicates that "species" is the specific epithet.
4	Species are organized alphabetically by genus (Throughout book). This becomes extremely noticeable and problematic in the "Turtles, Crocodiles, & Alligators" section (p. 147) when turtle species seem to be randomly present between crocodilian species.
5	"Relentlessly tightening its powerful coils, the mighty boa constrictor squeezes the last breath out of its victims, listening for their heartbeat..." (p. 21).
6	Description of a rattlesnake's rattle: "This is a series of horny shells…" (p. 38).
7	Tuatara is listed and classified under lizards (p. 130).
8	Why an amphibian section in a book entitled "Snakes and Reptiles"? (p. 165).

[1]Approximately 18,000 copies were sold estimated from the Amazon Best Sellers Rank (88,039 in Nov. 2011) where this rank is converted to the number of books sold per week using a logarithmic function (fonerbooks.com). This number is then used in a calculation (BeneathTheCover.com) to account for all national sales and years since publication.



PUBLICATIONS RECEIVED



Venomous Snakes of the World

by Mark O'Shea. 2011. Princeton University Press, Princeton, New Jersey (http://press.princeton.edu) and New Holland Publishers, UK. 160 pp. Softcover. US $19.95, £13.95. ISBN 978-0-691-15023-9.

Boas and Pythons of the World

by Mark O'Shea. 2011. Princeton University Press, Princeton, New Jersey (http://press.princeton.edu) and New Holland Publishers, UK. 160 pp. Softcover. US $19.95, £13.95. ISBN 978-0-691-15015-4.

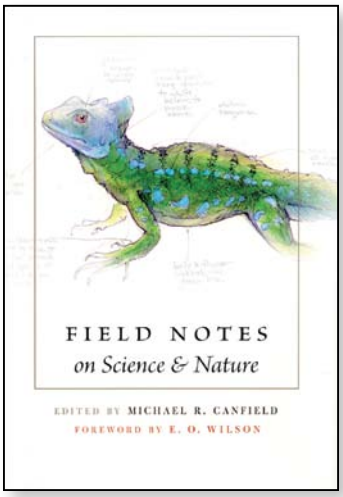
Both of these titles are newly issued softbound versions of books originally published in 2005 and 2007, respectively, with no changes evident. Both are characterized by outstanding color photography (ca. 150 images in each) and attractive graphics.

Venomous Snakes begins with an explanation as to which species are included in a book on "venomous" snakes, given the diversity of colubrid (*sensu lato*) species with some level of toxic secretions. The solution was to include those species whose bites are known or suspected to be dangerous. The book first presents a review of snake anatomy, with particular attention to features relevant for venomous snakes, followed by concise overviews of families of modern snakes containing venomous species, snake venoms and their actions, seasnake adaptations for marine living, and conservation. The snakes are then presented geographically: Americas, Eurasia, Africa, Tropical Asia, Australasia, and the Oceans.

An introductory section in *Boas and Pythons* provides current information about evolution, anatomy, diversity and distribution of basal snakes, constriction, giant snakes, man-eating snakes, and conservation. As in the preceding volume, the snakes are covered by geographic region. The book's title is a bit misleading, in that O'Shea includes all basal lineages (Scolecophidia + Alethinophidia), so readers might be surprised to see photos of blindsnakes alongside boas and pythons.

These attractive books are not only for a general readership, but also for herpetologists who will appreciate the beautiful photography of so many interesting species.

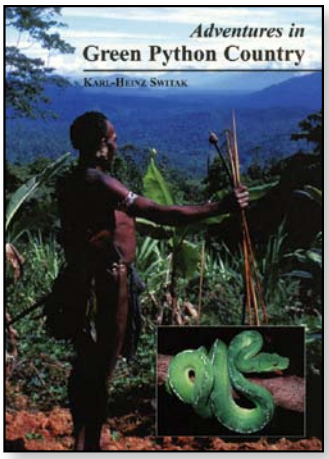
Reptiles de la Provincia de Río Negro, Argentina



by Gustavo J. Scrocchi, Cristian S. Abdala, Javier Nori, and Hussam Zaher. 2010. Fondo Editorial Rionegrino, Nequen. 249 pp. ISBN 978-9-507-67042-8. $140.00 pesos (about US $33.00) plus shipping and handling. Available from Fundación Miguel Lillo (Centro de Información Geobiológico del NOA / Biblioteca: Sra. Mariá Angela Prieto - maprieto@lillo.org.ar).

This is an important contribution documenting the reptiles from an extensive and diverse area from the Argentinian portion of Patagonia. Since many of the species contained in this book are not endemic to this region, it will also be useful for people interested in the reptiles of other Argentinian provinces and the surrounding countries of Chile, Bolivia, Paraguay, Uruguay, and the south of Brazil. This handy-sized book is illustrated by more than 130 color photographs and other images, including maps showing the location of museum specimens from the four major Argentinian museum collections. The book includes a brief description of Río Negro province, including its geography, geology, phytogeography, and a concise account of its land use and location of protected areas. There is an easy to follow and very useful identification key accompanied by illustrations of the diagnostic characters. The guide covers the only turtle known from this province, two amphisbaenians, 17 snakes, and about 50 lizards. For each one of the species there is a brief morphological description, including comparisons with similar species, an account of the localities where the species has been reported, including areas outside Río Negro, conservation status, and, in some instances, ecological information. For some of the species the different vernacular names applied to each species in different areas are presented.

Field Notes on Science & Nature



Michael R. Canfield (Editor). 2011. Harvard University Press, Cambridge, Massachusetts. 297 pp. Hardcover, US $27.95. ISBN 978-0-674-05757-9.

Despite the cover illustration, this is not a herpetological title, but nevertheless should appeal to field biologists of all stripes as well as those who simply enjoy observing nature. E. O. Wilson, in sharing examples from his own field notebook, introduces a collection of essays by eminent biologists who take readers into the field, sharing moments of exhilaration and inspiration, along with the inevitable challenges and drudgery that come with field work. All contributors stress the importance of recording field data, which might seem self-evident to most readers, but here we read of examples that emphatically reinforce that point. On display are various methods and systems for recording observations, especially useful for younger workers. George Schaller explains how he approaches study subjects (lions, mountain gorillas, giant pandas, etc.) and includes reproductions of pages from his field notebooks. Legendary birder Kenn Kaufman extols the virtues of list keeping, drawing examples from bird counts, Roger Kitching's skills as an artist/naturalist are displayed, and Jenny Keller offers a brief, but profusely illustrated, tutorial on making drawings in the field. Piotr Naskrecki explains his use of relational databases for organizing field data, likely an attractive option in this era of portable devices. John Perrine and James Patton provide an overview of the "Grinnell Method" of taking field notes, developed in the early 1900s by Joseph Grinnell, the visionary first director of the Museum of Vertebrate Zoology at UC Berkeley. This method has been adopted and adapted by legions of MVZ students and researchers, forming a data-rich historical foundation for vertebrate communities in California. In summary, this is an enjoyable read and an excellent resource for students.

Adventures in Green Python Country

by Karl-Heinz Switak. 2006. Natur und Tier – Verlag GmbH, Münster. 362 pp. Softcover, 39.80 Euros (approx. US $56.60). ISBN 978-3-937285-82-5. Available through Chimaira Buchhandelsgesellschaft mbH (www.chimaira.de).

Although published in 2006, this title remains barely known to most herpetologists. Karl-Heinz Switak is a native German who eventually became Supervising Herpetologist at the Steinhart Aquarium at the California Academy of Sciences in San Francisco. This book is another in a growing list of semi-autobiographical herp-adventure volumes in the spirit of Frank Buck and Carl Kauffeld. Switak recounts his travels to Indonesia, Australia, and most prominently, New Guinea, often in search of Green Tree Pythons. Although the writing at times seems as though from a different era, the large number of color photographs of herpetofauna (especially Green Tree Pythons), as well as people and places, make this a worthy addition to the bookshelves of herpetologists, python-keeping hobbyists, as well as those who enjoy reading about real-life adventures in exotic places.

THE FIFTH ASIAN HERPETOLOGICAL CONFERENCE
June 2-4, 2012 China

The Fifth Asian Herpetological Conference will be held on June 2–4, 2012 in the city of Chengdu, western China. The conference will be joined by the Annual Meeting of the Chinese Herpetologist Society and hosted by the Chengdu Institute of Biology and the Chinese Herpetologist Society. The conference is the largest regional herpetological gathering of the Asian and Pacific area and we anticipate that 250–300 herpetologists will attend the conference. This is a wonderful opportunity to meet friends, exchange ideas and establish collaborations. In addition to regular presentations, several workshops are also planned, which will provide a learning experience for students.

LOCATION AND VENUE:
Chengdu Eighteen-Step Island Hotel, Chengdu, Sichuan Province, China.
http://www.cdscjd.com/18bden/

WORKSHOPS:
1) Bioacoustics Analysis: Principle and Application
2) Research Methods or Experiment Designs
3) Major Topics in Evolutionary Herpetology

PRESENTATION SESSIONS:
1) Systematics and Biodiversity
2) Biogeography
3) Behavior and Physiology
4) Genetics, Development and Evolution
5) Ecology and Conservation
6) Snake Venom, Snakebite Prevention and Treatment
7) Captive Amphibians and Reptiles

For more information, please visit http://test.ox120.com/ahr/index.html or contact Dr. J. Fu at jfu@uoguelph.ca or Dr. Y. Tang at tangyz@cib.ac.cn

INFORMATION FOR CONTRIBUTORS

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes concerning the study of amphibians and reptiles, as well as book reviews, commentaries, regional and international herpetological society news, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (for information, please refer to: http://www.ssarherps.org/pages/JHinstr.php). To submit a manuscript to ***HR***, please consult the SSAR webpage at:

<http://www.ssarherps.org/pages/HRinfo.php>

REPRINTS AND PAGE PROOFS

Page proofs are sent electronically to authors of all articles, book reviews, and obituaries, but are not prepared for natural history, geographic distribution, or herpetoculture notes. Proofs are sent as pdf files approximately 2–4 weeks prior to publication. High resolution electronic (pdf) reprints of notes, articles, book reviews, and obituaries are provided at no charge to the primary/corresponding author as a benefit of SSAR membership. Reprint files will normally be sent prior to the issue mailing date from the printer. Authors who are not current SSAR members may purchase pdf reprints from the SSAR Publications Office.

ADVERTISING

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR web page (http://www.ssarherps.org/pages/HRinfo.php).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Central Michigan University, Department of Biology, 217 Brooks Hall, Mt. Pleasant, MI 48859, USA. Periodicals postage paid at Mt. Pleasant, MI 48859 and at additional mailing offices. All rights reserved. No part of this periodical may be reproduced without written permission of the Editor, except that authors and their agents are permitted to reproduce and distribute their own articles and notes. **POSTMASTER:** Send address changes to Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, UT 84158. **MISSING OR DAMAGED ISSUE?** Please notify Breck Bartholomew, SSAR Publications Secretary (e-mail: ssar@herplit.com) for a replacement.

SSAR PUBLICATIONS

SSAR publishes seven different series: *Journal of Herpetology, Herpetological Review, Facsimile Reprints in Herpetology, Contributions to Herpetology, Herpetological Circulars, Herpetological Conservation*, and the *Catalogue of American Amphibians and Reptiles* (see below for CAAR details). SSAR members receive prepublication discounts on all *Facsimiles* and *Circulars* and on volumes in the *Contributions* and *Herpetological Conservation* series. A complete pricelist of Society publications is available at: http://www.ssarbooks.com/.

CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available for purchase from the SSAR Bookstore (http://www.ssarbooks.com/). Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1–880	check website below for current pricing
INDEX TO ACCOUNTS 1–400: Cross-referenced, 64 pages	$6
INDEX TO ACCOUNTS 401–600: Cross-referenced, 32 pages	$6
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)	$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)	$35
INCOMPLETE SET: NUMBERS 1–190	$75
191–410	$85
411–840	$320

To order: make checks payable to "SSAR" and mail to Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, Utah 84158, USA (fax 801/453-0489). e-mail: ssar@herplit.com. Online orders at: http://www.ssarbooks.com/.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

www.ssarherps.org

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology,* and its news-journal, *Herpetological Review*, both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*.

To join SSAR or to renew your membership, please visit the secure online ZenScientist website via this link:

http://www.ssarherps.org/pages/membership.php

Future Annual Meetings
2012 — Vancouver, British Columbia, 8–14 August (with World Congress of Herpetology)
2013 — Albuquerque, New Mexico, 10–15 July (JMIH with ASIH, HL, and AES)

ABOUT OUR COVER: *Telmatobufo venustus*

The Chile Mountains False Toad is covered extensively in this issue (see Fenolio et al., pp. 514–519) but the unique, threatened area in which this rare creature lives is worth discussion. Recognized as one of the world's biological hotspots, the Chilean Winter Rainfall-Valdivian Forests Region (CWRVFR) is practically an island, albeit mostly surrounded by landforms. Unstable during the Eocene, under the ocean in the Miocene, and finally, profoundly modified by tectonic action during the late Pliocene and Pleistocene, CWRVFR was then subjected to glacial scouring. Bounded by the Pacific Ocean, the Andes Mountains, and the Atacama Desert, the region is covered by ancient forests of *Nothofagus*, *Araucaria*, and *Laurelia* dating from the Tertiary. These came into contact with tropical floras owing to the drastic geological changes. The resulting modern vegetation, like the fauna, reflects a high degree of endemism (Formas 1979. La herpetofauna de los bosques temperados de Sudamerica, pp. 341–369 *In* W. E. Duellman, Jr. [ed.], The South American Herpetofauna: Its Origin, Evolution, and Dispersal. Monogr. 7, University of Kansas Museum of Natural History, Lawrence).

Indeed, of the more than 40 species of amphibians in the CWRVF, the majority are unique to that region. Endemics include such oddities as *Rhinoderma* (two species), *Insuetophrynus*, *Calyptocephalella* (each with a single species), *Eupsophus* (several species), and *Telmatobufo* (with four species including *T. venustus*, the subject of our cover). *Rhinoderma darwinii* and *R. rufum* are considered flagship species for the region; the former is vulnerable "VU" while the latter is critically endangered "CR" (IUCN) or possibly extinct.

Overgrazing, invasive species, sedimentation and silting, urbanization, and logging are all contributing factors to the degradation of this habitat. Recent problems include development of coastal areas to foster tourism and the construction of major hydroelectric dams. A newly proposed dam project threatens the most pristine sectors of Patagonia. Many persons and institutions in Chile are concerned and struggling to protect her unique wilderness heritage, but the global economy and the country's burgeoning population make for a formidable obstacle. There is reason for optimism, both because of world conservation interest and the spirit in Chile, which abides by a local proverb: "No one has done well who has not suffered disillusionment."

Danté Fenolio (below), **Andrés Charrier**, and **Pilar Calderón** collaborated to produce the cover image. The frog was photographed on a mossy boulder at the site where it was encountered. A gold/silver mesh reflector and natural sunlight were used for illumination. A Sony Alpha 100 with a 10–20mm lens on a tripod with a 2.5-second exposure at f./20 with an ISO speed of 200, rendered the "foggy" look of the passing stream water.

Fenolio is the resident Amphibian Conservation Scientist for the Atlanta Botanical Garden's amphibian conservation program. His work with the Garden focuses on the population ecology of the Georgia Blind Salamander, *Eurycea* (=*Haideotriton*) *wallacei*, and in establishing assurance colonies of Chile's most threatened amphibian species at the National Zoo of Chile in Santiago. The first stage of the project, a breeding facility and captive assurance colony of Darwin's Frogs, *Rhinoderma darwinii*, now exists at the zoo and is producing offspring. New amphibians to the project include the cover species, *Telmatobufo venustus*. An avid wildlife photographer for most of his life, Fenolio is wrapping up a book focusing on wildlife that is adapted to darkness. Andrés Charrier and Pilar Calderón have been involved in the fieldwork in Chile for the Darwin's Frog Conservation Initiative. Both have made significant contributions to the project. Andrés Charrier (Centro de Estudios Avanzados de Ecología y Biodiversidad, Universidad Católica de Chile) now works on amphibian projects across much of south Chile.

PHOTO BY WILLIAM W. LAMAR

SSAR BUSINESS

2011 Annual Meeting, Minneapolis, Minnesota

The 54th Annual Meeting of SSAR took place from 6–11 July 2011 at the Hilton Minneapolis Hotel, Minneapolis, Minnesota, USA. The Organizing Societies were Society for the Study of Amphibians and Reptiles (in conjunction with the International Society for the History and Bibliography of Herpetology), American Elasmobranch Society (celebrating its 27th annual meeting), American Society of Ichthyologists and Herpetologists (celebrating its 91st annual meeting) and The Herpetologists' League (celebrating its 69th annual meeting). The meeting was hosted by University of Minnesota and St. Olaf College. The hard-working local hosts, Ken Kozak (Chair), Pat Ceas, and John Moriarty were assisted by the staff of Kansas State University Division of Continuing Education and many student volunteers.

Just over 850 herpetologists and ichthyologists from at least 27 different countries attended the 2011 JMIH. Following recent trends, this number was lower than last year. Almost 500 papers and approximately 250 posters were presented. Four symposia were held, including one in honor of the 80th birthday of John Legler ("Biology of Turtles of the Upper Mississippi River Basin: A Symposium in Honor of the 80th Birthday of John M. Legler and his 50 Years of Fieldwork with Turtles in the USA, Mexico, Central America, and Australia"). SSAR sponsored the symposium "Assisted Reproductive Technologies and Genetic Resource Banking: Tools for Conserving Declining

Amphibians." This symposium was organized by Jennifer Germano and Andy Kouba, who wish to thank SSAR and all of the participants and attendees. The symposium featured 14 speakers (ranging from graduate students to senior researchers) and was followed by a productive Skype-facilitated discussion that included colleagues from the UK, Russia, and Australia who were unable to be in Minnesota (Fig. 1).

After a busy day of Board and Executive Committee meetings, the 2011 JMIH began officially with the Plenary Session on the morning of July 7th. Ken Kozak, Chair of the Local Host Committee, welcomed attendees to the meeting and thanked the many student and postdoctoral volunteers, the JMIH Meeting Committee, and K-State for their hard work. He reviewed many of the upcoming social events and reminded people of the JMIH logo competition (see below). Susan Wells (Director, Bell Museum of Natural History, University of Minnesota) then welcomed us to Minneapolis and affirmed the importance of studying the whole organism. President Joe Mendelson summarized some SSAR events to look out for over the next few days, particularly the Ernie Liner Mardi Gras Live Auction. ASIH representatives presented a number of awards (the Robert Gibbs Award to William F. Smith, the Fitch Award to Raymond Semlitsch, and the Johnson Award to Henry Mushinsky). Cathy Bevier announced the second winner of the Meritorious Teaching Award in Herpetology, Dr. Robert Powell (Avila University). With this award, Bob (long time SSAR member and former editor of *Catalogue of American Amphibians and Reptiles*) is recognized for his exceptional accomplishments and contributions to herpetological education, particularly at the undergraduate level. Priya Nanjappa presented two awards from PARC (Partners in Amphibian and Reptile Conservation): the Alison Haskell Award for Excellence in Herpetofaunal Conservation to Alvin Breisch, and the Visionary Leader Award to Whit Gibbons.

AES Plenary speaker Kenneth Goldman gave a presentation on "The History of Studying Endothermy in Fishes: How many Places can you Stick a Thermometer?" He reviewed the history of temperature measurements, spoke about the many important contributions of Frank Carey, and reviewed the development of our understanding of endothermy in fishes.

Aaron Bauer, HL Distinguished Herpetologist for 2011, then spoke on "Hands, Sands, and Southern Lands: Geckos in Time and Space" during which he recalled 29 years of "geckomania," including 70 trips to Africa, 40 trips to Australia and the Pacific, 20 trips to tropical Asia, and over 100 trips to Europe. During these many trips, there were no deaths or serious injuries, however, he contracted one tropical disease, was involved in the destruction of two cars, and had one specimen stolen by a meerkat. Aaron spoke of the long, independent evolutionary history of gekkotans and the many factors that make them unique, particularly toe adhesion. In closing, Aaron, in his position as Secretary General of the World Congress of Herpetology (WCH), issued an invitation to next year's 7th WCH in Vancouver.

James Hanken was the last Plenary speaker of the morning and gave the ASIH past-Presidential address on "Plotting the Future of Comparative Biology." He views this as being both a very exciting time to be a comparative biologist, with the discovery and description of many new species in an "age of taxonomy," as well as a tragic time, with the increasing loss of biodiversity and threats to museums and natural history collections, with recent budget cuts and job losses. Jim noted declining memberships in many taxonomically-based societies, including some herpetological societies (although commenting that this is not the case for SSAR). He voiced concern of a growing recognition by some that our fields are too highly fragmented and that we lack a united voice. He indicated that changes in the ways professional societies operate and view themselves are likely if they are to continue to remain viable and have any meaningful impact on our field (e.g., more strategic actions, an increasing focus on the "big picture," greater collaborations among the societies) and suggested that we must play a more active role in counteracting the views expressed in reports such as that of U.S. Senator Tom Coburn on NSF. Jim is currently serving as chair of an AIBS Ad Hoc Committee on Biodiversity-related Sciences. The charge to this committee is to gather information on the feasibility of a biodiversity-related science policy initiative and submit a report on their findings by the end of this year. Jim's take-home message was that taxon-based societies can, and should, play an essential role in planning the future of comparative biology, but that they also need to change the way they do business if their efforts are to be effective.

Thirteen images were submitted to the JMIH logo competition. Attendees cast their vote for their favorite logo throughout the meeting. Congratulations to the winner, Kevin Wang. The image he created is now being used on the JIMH website (http://www.dce.k-state.edu/conf/jointmeeting).

Social and Professional Events

Phil Bishop (University of Otago, New Zealand) kicked off SSAR's many contributions to the 2011 JMIH with his President's Travelogue on the evening of July 6th. Phil spoke on "An Austral Perspective: Herpetological Adventures South of the Equator." He documented his travels and research on amphibians in South Africa, New Zealand, Australia, and Fiji. Phil was recently appointed by the IUCN as Chief

PHOTO BY M. PREEST

Fig. 2.

Scientist for the Amphibian Survival Alliance (ASA) and he gave a paper a few days later on the activities of the ASA ("The Amphibian Survival Alliance Jumps into Action").

The now-annual SSAR/HL Student Reception was held late afternoon on July 7th. The room was packed with students and invited professional herpetologists. President Mendelson gave a warm welcome to our student members and encouraged them to enjoy finger food, drinks, and meeting senior herpetologists (Figs. 2, 3). The student reception was followed by the Joint Meeting Reception. A short bus ride delivered us to the Nicollet Island Pavillion in the middle of the Mississippi River (Fig. 4). A stroll around the southern end of the island followed dinner for some, while others were content to sit and catch up with friends and colleagues (Fig. 5). The group photo (by Matthew D. Potenski) was taken outside the Pavillion (http://www.dce.k-state.edu/conf/jointmeeting/images/jmih2011_group.jpg).

Dawn Wilson and Robert Espinoza organized a highly successful and well-attended lunch-time student workshop, "Law and Order in Herpetology: Permits and Regulations for Importation and Exportation" (held on July 8th). Seven panel members from the zoological, museum, conservation, non-profit, and academic communities talked about their experiences obtaining permits to work in countries other than the US, as well as permits to import live and preserved material (Fig. 6). Attendance by students was so high that we ran out of pizza (sorry—we promise more next time!). The panel members had lots of great advice and responded to many questions from the audience, e.g., how to handle importation of specimens not definitively identified.

This year's very special Live Auction, the "ASIH/HL/SSAR Ernie Liner Mardi Gras-Auction" was held on July 10th. Ernie, a long-time member of The Ohio Herpetological Society and SSAR, and a former member of the Board of Directors passed away in September of 2010. The auction consisted entirely of materials from Ernie's estate that were donated to the three societies. Brian Crother (then SSAR President) and a number of his students from Southeastern Louisiana University (Chris Murray, Justin Rheubert, Jenifer Lee, and Ryan Willis) worked hard over several days to pack the materials Ernie had donated to the societies. Breck Bartholomew arrived in Houma, Louisiana with a 26-foot U-Haul truck and Brian, Breck, Chris, and Justin spent 10–12 hours simply loading the truck. Breck transported the collection to Salt Lake City and it is being processed for sale through online auction. SSAR is very grateful to Breck, Brian, and Brian's students for their work on behalf of the societies.

Breck showed up in Minneapolis with less than 1% of Ernie's collection. The range and quantity of items was truly impressive—books, jewelry, door mats, stuffed, blow-up, and plastic animals, porcelain figurines, snake sticks, artwork, fridge magnets, caps, bottles of herpetologically named wine, mugs, glasses, t-shirts, ties, newspaper clippings, and even Ernie's honorary doctorate diploma, mortar board, and hood from the University of Colorado! Auctioneers Brad Moon, John Moriarty, Steve Mullin, and Aaron Bauer were ably assisted by Greg Watkins-Colwell and a small and busy army of students (Heather Heinz, Jolene Rearick, Alicia Kennedy, Brittany Barker, and Jenny Gubler). President Mendelson created a slide show of Ernie's life that ran throughout the evening. Bidding on many items was spirited and the auction ran close to midnight. It was an appropriate way to celebrate Ernie's life and contributions to herpetology and it will be difficult to top the 2011 Live Auction (Figs. 7–9).

Breck also displayed many items from Ernie's estate at the SSAR Publications booth (Fig. 10). For a small donation to either the Ernie A. Liner or the Roger Conant Endowments one could select from an array of objects. Not many people left Minneapolis without an Ernie Liner fridge magnet!

Mike Jorgensen and Vinny Farallo organized this year's Silent Auction. The silent auction changed location this year in an effort to increase visibility and could be found outside the Plenary Session entrance in the main break area. Donors this year included Kraig Adler, Ronn Altig, Breck Bartholomew, The Herpetologists' League, Allen Press, and University of California Press, and helped to bring in US $1763 for the SSAR Student Travel Fund (more than doubling amounts earned in previous years). Once again, the ten recipients of the US $400 SSAR Student Travel Award (Fig. 11) took turns to work the silent auction table for 2–3 hrs throughout the course of the meetings; all agreed that this "service" was a great way to meet new colleagues at the meeting.

The end-of-meeting Banquet was held on July 11th. Larry Allen again served as Master of Ceremonies. On behalf of the JMIH Societies, he thanked the local hosts and K-State for another enjoyable and successful meeting. Larry then introduced those at the head table (including President Mendelson, Treasurer Nicholson, and Secretary Preest) and asked past-presidents of the societies in attendance to stand (including four past-presidents of SSAR). ASIH election results were announced, certificates of appreciation were presented, and resolutions were read. Various awards from ASIH, AES, and HL were announced. Pat Gregory (University of British Columbia) issued an enthusiastic invitation to herpetologists *and* ichthyologists to attend the World Congress of Herpetology in Vancouver, 8–14 August 2012. Larry thanked those in the room for attending what could be the penultimate traditional banquet and promised a "highly modified version" of the end-of-meeting banquet at the 2013 JMIH (10–15 July) to be held in Albuquerque, New Mexico.

Board, Long Range Planning, and Business Meeting Summaries

SSAR Board Meeting

Society President Joseph Mendelson called the Board Meeting to order at 0805 hrs on July 6th, 2011 in the Hilton Hotel, Minneapolis, Minnesota. In attendance were the following members of the Board of Directors, Editors, and Committee Chairs: Kraig Adler (Editor, *Contributions to Herpetology*; Chair, Long Range Planning Committee), Bob Aldridge (President-Elect), Breck Bartholomew (Publications Secretary), Aaron Bauer (Editor, *Facsimile Reprints in Herpetology*), Cathy Bevier (Chair, Herpetology Education Committee), Rafe Brown (Chair, Seibert Award Committee), David Cundall (Board Member, Reg. 2012), Raul Diaz (Webmaster), Kevin de Queiroz (Board Member, Reg. 2012), Tiffany Doan (Board Member, Reg. 2014), Richard Durtsche (Coordinator, Symposium Committee), Pat Gregory (Board Member, non-US 2012), Robert Hansen (Editor, *Herpetological Review*), Mike Jorgenson (Chair, Silent Auction Committee), Joseph Mendelson, III (President), John Moriarty (Editor, *Herpetological Circulars*), Erin Muths (co-Editor, *Journal of Herpetology*), Kirsten Nicholson (Treasurer), Ann Paterson (Board Member, Reg. 2012; Chair, Membership Committee), Gad Perry (co-Editor, *Journal of Herpetology*), Marion Preest (Secretary), Al Savitzky (SSAR Representative to AIBS and BioOne), Carol Spencer (Board Member, Reg. 2014), Greg Watkins-Colwell (Chair, Nominations Committee; Organizer, SSAR/HL Live Auction), and Dawn Wilson (Chair, Student Participation Committee). Additional society members present included Robin Andrews, Marina Gerson, and Henry Mushinsky. Introductions were made and minutes of the 2010 Board of Directors Meeting (Providence, Rhode Island) were approved.

Annual reports for 2010/2011 were submitted by all Officers, Editors, and Committee Chairs.

Officers' Reports.—President Joseph Mendelson reported that SSAR was involved as a Festival Partner with the USA Science & Engineering Festival in Washington D.C. in October, 2010. The first of the 2011 issues of *Journal of Herpetology* and *Herpetological Review* revealed changes in formats and increased use of color. Joe extended kudos to Editors Bob Hansen, Erin Muths, and Gad Perry. A Zoo Atlanta volunteer has begun the important and long-awaited task of completing and copyediting the indexing effort for *Herpetological Review*. This will allow *Herp. Review* to be searchable and posted in online databases. President Mendelson was involved in the work of the Long Range Planning Committee, the Membership Committee, and the JMIH Meeting Management and Planning Committee. He reported writing or signing a number of letters pertaining to SSAR business over the past year and made arrangements for Phil Bishop to be the 2011 SSAR President's Travelogue speaker. Joe was also involved in receiving the estate from Ernie Liner and organizing the three-society auction in Ernie's memory.

Past-President Crother reported appointing Kraig Adler as chair of the Long Range Planning Committee, Ann Paterson as chair of the Membership Committee, Raul Diaz as Webmaster, and Rafe Brown as chair of the Seibert Awards Committee. The EBSCO contract that was approved by the board at the 2010 meeting was completed and signed. Brian sent a letter of thanks to Thomas Beauvais for his generous donation to support increased use of color in our journals. He reported that, following discussion after the 2010 JMIH, the SSAR Board voted to approve changes to the Meeting Management Committee to make it a JMIH committee rather than an ASIH committee.

Treasurer Kirsten Nicholson reported that, overall, the finances of SSAR are quite sound and that 2010 was a good year for us. Expenses

PHOTO BY ROBERT HANSEN

FIG. 4. Sundown on the Mississippi River, looking into downtown Minneapolis, as seen from the Nicollet Island Pavillion, site of the Joint Meeting Picnic.

were less than expected and income higher than expected, resulting in a net profit of $52,433. In addition, the stock market has steadily increased and our portfolio has returned to its pre-crash levels (as of May 2011). In our first year of participating as partners in the JMIH finances, SSAR paid approximately $500 to ASIH for SSAR-specific costs. Kirsten indicates that, in terms of our journals, we generally perform at the very edge of our expenses. We will have to increase our income to accommodate changes to the journals. The approved 2010 budget was balanced and about half of our expenses were over-budget with half under or right on budget, although overall we came in under-budget. Breck Bartholomew took over membership management and the society should be extremely grateful, as the cost to us is vastly less than we had with Allen Press, Inc. Our income from memberships was greater than anticipated and the number of members has increased from last year for both individual and institutional subscriptions. The Publications Office went over-budget, but that is largely due to the expenses incurred handling the Ernie Liner collection. Due to the nature of this year's auction, no funds will be collected in support of student travel. The Society's investments increased slightly during 2010, in keeping with the trends in the global market. The total market value increased 15% from US $493,004 to an ending value of US $571,156, although the book value increased by only 2%. As of May 2011, we had returned to our pre-crash values of over US $600,000, but this last month has seen a dive below US $600,000. The general strategy Kirsten has been employing is a balance between growing our investments as best we can, given our total circumstances, yet allowing for increased spending as it pertains to our initiatives.

Secretary Marion Preest provided Officers, Editors, and Committee Chairs with minutes of the 2010 Board Meeting and summarized the 2010 Annual Meeting for publication in *Herp. Review*. She keeps track of changes in personnel and regularly updates SSAR letterhead, informs the Editors of *Journal of Herpetology* and *Herp. Review* of these changes, and provides various updates to Webmaster Raul Diaz. She routinely writes letters to student winners of awards (e.g., Kennedy, GIH, etc) and prepares announcements for publication in *Herp. Review*. Marion compiled the 2011 Annual Report and prepared agendas for the Board and Business Meetings for the 2011 JMIH. She again organized a reception for student members of SSAR and HL to be held at the JMIH. There was some discussion by the Board of non-students and individuals who are not members of either SSAR or HL registering for the reception. We are trying to balance a desire to make this an open and inclusive event with our ability to cover costs. Marion corresponded with the Board regarding various issues that needed a vote, e.g. renewal of the JMIH memorandum of understanding, approval of JMIH symposia, etc. She ensured that SSAR members who do not provide email addresses to the membership office received paper ballots for the 2010 election. Voting participation (both electronic and paper) was again very low, even though electronic voting this year did not require login or a password, and thus was very simple. A suggestion was made that we publish a notification of upcoming elections in *Herp. Review* and/or on the website. Those who wish to vote, but are not able to do so electronically, could contact the Secretary and request a paper ballot.

Publications Secretary Breck Bartholomew reported that total income from the Publications Office in 2010 was US $57,715.13. He is requesting a budget for 2011 that includes funds to process the Ernie Liner bequest, which will eventually be paid back from proceeds from the sales. Breck would like to remainder books that are no longer selling well enough to justify storage space. The Board suggested that, prior to remaindering the books, Breck make them available to members at deeply discounted prices (plus costs of postage) and that he send them to libraries at academic institutions for outreach purposes. Joe asked that Breck summarize the discussion of the Board and then provide the Board with an outline of how he wishes to proceed, e.g., sell, give away, remainder.

George Pisani (Trustee) reported that he again filed SSAR's annual corporate report with the Office of the Kansas Secretary of State.

Editor's Reports.—Andy Price, Editor of *Catalogue of American Amphibians and Reptiles*, reported that accounts 881–900 (2 gymnophiones, 3 salamanders, 3 frogs, 2 turtles, 7 lizards, 3 snakes) will be published sometime this year. Andy suggested that the Board needs to make a decision about the future of *CAAR* in light of his decision to resign as Editor and difficulty in recruiting editors and authors. He raised two possible options. The first is to cease publication of *CAAR*. The second is to go digital and publish an account on the website whenever one is ready. Andy indicated that he is willing to modify his decision to resign if the Board approves the second option.

Kraig Adler, Editor of *Contributions to Herpetology*, reported that "*Biology of the Reptilia*, Volume 22, *Comprehensive Literature of the Reptilia*, by Ernest A. Liner was published in March 2010 and "*Snakes of Honduras*" by James McCranie was published in March 2011. "*Herpetology of Armenia and Nagorno-Karabakh*" (by Marine Arakelyan, Felix Danielyan, Claudia Corti, Roberto Sindaco, and Alan Leviton), will be published in late 2011. "*Contributions to the History of Herpetology*," vol. 3 (by Kraig Adler, John S. Applegarth, and Ronald Altig), "*A Contribution to the Herpetology of Northern Pakistan*" (by Rafaqat Masroor), "*A Guide to the Snakes of the Philippines*" (by Rafe Brown, Alan Leviton, Maren Gaulke, and Arvin Diesmos), "*Field Guide to Amphibians and Reptiles of the West Indies*" (by S. Blair Hedges), and "*Lizards of Southern Africa*" (edited by William R. Branch and Aaron Bauer) are planned beyond 2011.

Editor Aaron Bauer (*Facsimile Reprints in Herpetology*) reported that no new titles were published in the past year and a single publication is planned for 2012 (Duméril and Bibron's "*Erpétologie Générale ou Histoire Naturelle Complète des Reptiles*" (1834–1854) [to be guest edited by Kraig Adler]). As the result of a generous donation, Aaron expects to be able to sell this *Facsimile* at < US $300. This is a very large, multi-volume *Facsimile* and the costs of shipping (especially overseas) and storage will be high. Various options to reduce weight, e.g., combining individual volumes, are being evaluated. A suggestion was made to especially encourage prepublication sales so as to reduce storage costs by not overproducing. Eventually an electronic version will be available, but currently demand is for a paper copy. The majority of projects planned beyond *Erpétologie Générale* are in various states of completion and are collected works *Facsimiles*.

Aaron reported that, in consultation with Greg Watkins-Colwell, he had made the decision to cancel a reprint of J. E. Gray's series of catalogues of the amphibians and reptiles in the collection of the British Museum. Aaron believes that the playing field for *Facsimiles* has changed fundamentally recently and that serious reconsideration of the *Facsimile Reprints in Herpetology* series is required. The historical role of the *Facsimiles* series was to serve the herpetological community by making available difficult-to-obtain older literature, chiefly works of real utility to some subset of our community. The exponential increase in the availability of literature however has effectively narrowed SSAR's niche in this field. Aaron has come to the conclusion that it is not cost effective to continue with the reprinting of most single-volume titles that are 1) available through literature portals, and 2) do not have illustrations or have only simple black and white illustrations that reproduce well in electronic copy and hard-copy printouts therefrom and thus, that only certain types of publications are likely to be viable projects for reprints. The upcoming

facsimile of Duméril and Bibron is a case in point. This work, in addition to being very widely used and needed by the community, has many color plates, is represented online by relatively poor scans, and is so large as a whole that it is rather awkward to work with in an online format. Likewise, Aaron believes that the collected works of single authors (e.g., Peters, Peracca, Smith, etc.) are also strong candidates for facsimiles. These include tens to hundreds of individual publications that would be difficult for readers to assemble, even if most are available in some electronic format. They also provide complete annotated bibliographies and can include cumulative indices that offer added value. A third type of product might be a facsimile of a foreign language work with a complete English translation (a competing publisher has, for example, recently published a facsimile and translation of Laurenti's [1768] Latin work). There was brief discussion of Aaron's report and the Board indicated its trust that Aaron would do what is best for the series.

John Moriarty (Editor, *Herpetological Circulars*) reported that HC-39 (*A Guide to Tissue Collection, Preservation, and Management for Reptiles and Amphibians*) is in preparation, with publication planned for late 2011. The Seventh Edition of the *Scientific and Standard English Names of Amphibians and Reptiles of North America North of Mexico* will be published as HC-40. The revision will be given away at the World Congress in Vancouver in 2012.

Joe Mitchell, Editor of *Herpetological Conservation*, reported that no inquiries for publication were received in 2010 and that no progress was made on the book covering herpetological conservation in agricultural landscapes.

According to Editor Robert Hansen, *Herpetological Review* continues to operate smoothly. Volume 41 consisted of 528 pages and Volume 42 is projected to run >600 pages. Personnel changes include Robert Reed (Associate Editor) stepping down and Jodi Rowley, Felix Cruz, Priya Nanjappa, and Wulf Schleip joining the staff as either Associate or Section Editors. Support from the Thomas Beauvais Fund permitted an increase in the selective use of color and the last half of 2010 brought a flurry of activity. Following board approval, many things were set in motion including recruiting new editorial personnel, hiring a professional design team (Eagle Mountain Publishing), developing new content sections, soliciting contributions, and evaluating design options. The first edition of the redesigned *Herp. Review*, featuring full color throughout, appeared in March 2011 and has been received favorably. Beginning in 2011 (vol. 42), Bob initiated a new section (Conservation) to better reflect the importance of conservation-related issues in herpetology. He also created a new section for the publication of captive-based observations (Herpetoculture Notes) and resurrected a long-dormant feature (Institutional Profiles) with the first contribution appearing in the June 2011 issue. Another section (National and Regional Organizations) will debut later in 2011.

Full-issue pdf files of *Herp. Review* are available to SSAR members on the ZenScientist website. To promote membership in SSAR, copies of the new *Herp. Review* were distributed *gratis* to attendees at the All Florida Herpetology Conference in April. Reciprocal advertising agreements have been reached with a number of other publications/organizations that will permit SSAR to advertise membership/subscription options. As mentioned in President Mendelson's report, a comprehensive index to back issues of *Herp. Review* is in the works.

Editors of *Journal of Herpetology*, Erin Muths and Gad Perry report that former Editor, Geoff Smith, continues to provide editorial assistance and that the current Associate Editor roster contains some new names. In order to save money and better fit the standard pdf page size for electronic reprints, the Journal switched format in 2011. This also allows it to be bundled with *Herp. Review* for mailing, providing further savings. Erin and Gad reported that overall submissions set a new record in 2010. Submissions so far for 2011 (115) are similar to the number submitted during the same period in 2010 (135) and much higher than during 2009 (61). Rejection rate has remained fairly stable over the past few years. The amount of time needed to reach an initial decision remains similar to that in the past few years. Duration to reach a final decision peaked for manuscripts accepted in 2009, but has been reduced in 2010 to the lowest level Allen Press reports for our journal. There is currently approximately a 9-month wait between acceptance of a paper and publication. Erin and Gad expect to be able to maintain these numbers, or improve on them, in 2011. The biggest challenge to doing so is obtaining timely reviews. Securing willing, capable, and available Associate Editors is becoming quite difficult as well. The USA remains the leading source of manuscripts. Brazil is consistently the second largest source of submissions. Argentina also tends to be high, as are Australia, China, and Mexico. The larger number of manuscripts from non-English speaking countries places an added burden on the editorial process. The Editors note that they need to find a Brazilian Associate Editor.

The Editors conducted a quality analysis this year using the ISI Impact Factor. Overall they feel that our position is strong and continues to improve, but they would like to see it advance even further.

Committee Chair Reports.—The Conservation Committee (Betsie Rothermel, Chair) took action on a number of significant items during the past year: a) they sent comments to the U.S. Fish and Wildlife Service (USFWS) regarding designation of critical habitat for the Mississippi Gopher Frog, specifically expressing concern that the proposed "buffer radius" was too small and that greater emphasis

PHOTO BY M. PREEST

FIG. 5.

PHOTO BY M. PREEST

FIG. 6.

should be placed on habitat quality and management issues within the areas considered for inclusion; b) in response to the USFWS issuing a Notice of Inquiry regarding a petition to list all live amphibians in trade as injurious unless free of *Batrachochytrium dendrobatidis* (*Bd*), they prepared and submitted an extensive report summarizing the current scientific knowledge of the biology of *Bd*, its impacts on amphibians in the U.S., and surveillance and control techniques. They expressed support for the concept of regulations to help control the spread of this pathogen, but argued that focusing solely on *Bd* was short-sighted and suggested that USFWS should also consider other emerging pathogens in the development of any regulations and control measures; c) they sent a joint letter to key House and Senate representatives asking them to preserve funding for the State Wildlife Grant (SWG) and North American Wetland Conservation Act programs.

Joe Beatty (Chair, Dean Metter Award Committee) received 27 proposals this year and two winners were chosen. They are: Brandon Fessler, an M.S. student in the Department of Biological Sciences at Central Washington University in Ellensburg, Washington, whose dissertation research deals with seasonal behavior, habitat use, and spatial ecology in *Dicamptodon tenebrosus*; and Jessica Wood, a Ph.D. student at the University of Missouri, Columbia, whose research will analyze call plasticity and mate recognition in *Hyla femoralis*.

Chair of the Grants-in Herpetology Committee, Josh Kapfer, received 49 proposals this past year. Most applications were in the "Laboratory Research" category. The winners each receive US $500 and they are:

Conservation - Anne G. Stengle, University of Massachusetts

Education - Michelle Lester, Yakima Area Arboretum

Field Research - Michael Habberfield, State University of New York, Buffalo

Laboratory Research - Beck A. Wehrle, California State University, Northridge

Travel - Denita M. Weeks, California State University, Northridge

International - Kerry L. Holcomb, Central Washington University

Josh reported that reviewer criteria were implemented this year to streamline the review process and reduce subjectivity in evaluations. Additionally, the deadline for proposal submission was moved to 15 December in the hopes of easing the burden on reviewers.

The organization of the SSAR-GIH announcement was re-worked after the 2011 grant submission deadline. This decision was based on questions received from potential grant applicants prior to the 2011 submission deadline. The new announcement is on the website.

The 19th annual Seibert Awards Competition (Pat Owen, Chair) was run at the 53rd Annual Meeting of SSAR in Providence, Rhode Island. There were 35 eligible presentations. The Seibert Award winners for 2010 were: **Systematics/Evolution**: *Cameron Siler* and Rafe Brown, University of Kansas, "Historical processes behind patterns of limb reduction and loss in an island radiation of fossorial lizards." **Ecology**: *Jennifer Stynoski*, Virginia Noble, Meredith Strider, University of Miami, Organization for Tropical Studies, University of Maryland, "To eat but not to be eaten: honest begging signals and visual detection of predators and mothers by tadpoles of the Strawberry Poison Frog (*Oophaga pumilio*)." **Physiology/Morphology**: *Denita M. Weeks* and Robert E. Espinoza, California State University, Northridge, "Geckos on ice: unexpected thermal tolerances and temperature-dependent performance of the world's southernmost gecko." **Conservation**: *Daniel Leavitt*, Texas A&M University, "*Sceloporus arenicolus*, an endemic lizard in an endangered ecosystem."

Honorable mentions were: **Systematics/Evolution**: *Philip L. Skipwith*, Aaron M. Bauer, and Todd R. Jackman, Villanova University, "Molecular phylogenetics of New Caledonian diplodactylid geckos." **Ecology**: *Oliver Hyman* and James P. Collins, Arizona State University, "Negative influence of phosphorus on prevalence of the frog killing pathogen, *Batrachochytrium dendrobatidis*." *James Paterson*, Brad Steinberg, and Jacqueline Litzgus, Laurentian University, Algonquin Park, "Comparisons of hatchling survivorship and spatial ecology between two sympatric turtle species."

All winners received a check for US $200 and a book from University of California Press compliments of Chuck Crumly.

Cathy Bevier (Chair, Herpetology Education Committee) indicated her decision to step down as chair of this Committee. The Herpetology Education Committee continues to update the committee website and to respond to various enquiries submitted to the Herp Hotline. Members have also been active in developing and encouraging educational activities in herpetology. The Committee received support in 2009 from SSAR, HL, and ASIH for a proposal for a Meritorious Teaching Award in Herpetology. Ten nominations were received and considered by a Committee consisting of professional and student members of the three participating societies. The winner for 2010 was Dr. Whit Gibbons.

Kennedy Award Chair, Lynnette Sievert, announced that the winning paper for 2010 is by Cameron Siler (co-authored with Arvin C. Diesmos and Rafe M. Brown), "New Loam-Swimming Skink, Genus *Brachymeles* (Reptilia: Squamata: Scincidae) from Luzon and Catanduanes Islands, Philippines." Journal of Herpetology 44:49–60. Cameron will receive a check for US $200 or $400 equivalent in SSAR publications.

Robert Hansen, Kris Kaiser, Roy McDiarmid, Jim Murphy, Ann Paterson, Gad Perry, Marion Preest) was established in late 2010 by then-President Brian Crother. After familiarizing itself with the SSAR budget and several rounds of discussion, the committee submitted a series of recommendations to the Board in November regarding changes to *Herp. Review*. Since then, the committee has dealt with a number of issues including a proposal to increase membership dues and institutional subscriptions, a proposal from Allen Press to co-publish *Journal of Herpetology*, a proposal to assume management of *Contemporary Herpetology*, and a revision of the Society's website. In its deliberations, many members of the LRPC have pointed out that our website needs to be revised to make it more user-friendly (both for members and for SSAR officers and editors who need to revise or post information) and needs to be expanded to make it more beneficial for our membership. To date, the SSAR website has been staffed by loyal volunteers who have done a remarkable job, but our site no longer fully serves the many needs of our broad-based clientele. It was clear that only a few members of the LRPC had the necessary knowledge to contribute to this discussion, so a subcommittee was formed consisting of Bob Hansen, Breck Bartholomew, and Raul Diaz. Kraig asked them for a report by June 1st. This report was shared with the full LRPC and then discussed.

Kraig Adler ended his report with some personal comments regarding his view of the state of SSAR. His tone was optimistic and he particularly noted the recent increase in society membership, the receipt of the Special Libraries Association Award in 2009, the recent changes in *J. Herp.* and *Herp. Review*, and the important role of the Membership Committee. He also commented on the opportunities that will be presented to, and must be capitalized on by, SSAR at the WCH in 2012. Ann, Breck, and Kraig will work on producing a membership brochure to include with registration materials at the WCH. Joe will ask for assistance with this from the Media Department at Zoo Atlanta.

In his capacity as President, Joe Mendelson serves as SSAR representative on The Meeting Management and Planning Committee (MMPC). The Committee met in Minneapolis in March to develop a meeting schedule and review conference facilities. Future meetings are to be held as follows:

2012 — Vancouver (WCH)

2013 — Albuquerque

2014—TBA, possibly in the southeastern USA

Joe indicated that is it not entirely clear what role SSAR representatives will have in organizing the WCH, as the JMIH Planning Committee has no plans to meet before the 2012 meeting. Pat Gregory (Chair, WCH Vancouver Local Committee) indicated that abstracts will be submitted directly to WCH and the WCH Program Committee will put together the program. He is asking for symposia requests from SSAR, ASIH, and HL. Pat received some materials from Brian Crother two years ago describing SSAR's meeting requirements. He will send this to Joe for review. Pat promises "all the SSAR events without the work!" In terms of finances, each Society will cover the costs of society-specific events, e.g., room charges. The SSAR Board of Directors approved another three-year MOU that formalizes the JMIH in terms of cost- and profit-sharing.

Bob Cashner, chair of the JMIH Meeting Management and Planning Committee, reported that when the committee met in March there was discussion of a strategy of engaging hotel chains in multi-year contracts as a possible way to have less expensive accommodations. This has not been fruitful, however, the MMPC and K-State support efforts to find hotels that will reduce some of our meeting expenses.

Two symposia are already planned for 2012: "Biogeochemical Methods to Study Ectotherm Ecology and Physiology" (Chair: Sora Kim, sponsored by AES and ASIH); and "Technology and Innovation in Herpetology and Ichthyology Collections" (co-Chairs: Greg Watkins-Colwell and Mark Sabaj Perez), sponsored by SSAR, HL, and ASIH.

Bob Cashner also commented that committee members were aware of criticism of the JMIH and of suggestions that smaller meetings of a subset of the societies be considered. He remarked that we get the best offers from hotels when we fill our room blocks. A possible university venue was investigated for 2013, but without success. The MMPC has responded to concerns about costs by plans to cut the length of the meeting, replacing the banquet with an alternative activity, and selecting cities that allow for flights from a variety of starting locations.

Ann Paterson, Chair of the Membership Committee, assembled a committee of volunteers from a variety of backgrounds. During 2010–2011, the Membership Committee: 1) discussed and compiled a list of current membership benefits; 2) compiled a list of possible future benefits that could be offered; 3) prepared surveys of current SSAR members and of non-members to better understand the interests of these constituencies; 4) contacted varied organizations and outlets to attempt to survey a wide range of both members and non-members; 5) distributed a link to both surveys on the ZenScientist site; 6) compiled survey results to date as a basis for discussion; and 7) developed a proposal of ideas to pursue in 2011–2012.

FIG. 9.

The Nominations Committee (Greg Watkins-Colwell, Chair) compiled a list of nominees (see below) for the positions of President-Elect, Regular Board Member, Conservation Board Member and At-Large Board Member. Kirsten Nicholson and Marion Preest were willing to run again for the positions of Treasurer and Secretary respectively. *President-Elect*: Robert Aldridge, Frank Burbrink; *Treasurer*: Kirsten Nicholson; *Secretary*: Marion Preest; *Board Member* (*Regular*): Tiffany Doan, Lisa Hazard, Carol Spencer, Greg Watkins-Colwell; *Board Member* (*Conservation*): Jennifer Pramuk, Priya Nanjappa; *Board Member* (*At-Large*): Tony Gamble, Travis LaDuc.

Resolutions Chair, Robert Denton, presented resolutions at the SSAR Business Meeting in Providence in 2010. These have been published in *Herp. Review*.

Brian Crother, Chair of the Standard English and Scientific Names Committee, indicated that the 7th edition of the Standard English and Scientific Names List will be available online by the time of the 2011 JMIH. He thanks Raul Diaz (webmaster) and the members of the Committee. Each update of the online version will be given a different name, e.g., Version 6.0, 6.1, 6.2, etc. For the WCH in 2012, we will produce a hard copy to be distributed free to all of the meeting participants. The names list is sanctioned by SSAR, HL, ASIH, the Canadian Association of Herpetology, the Canadian Amphibian and Reptile Conservation Network, and Partners in Amphibian and Reptile Conservation (PARC).

Dawn Wilson reported that SSAR held a pizza lunch and workshop ("Grants: What is out there and how to write a successful grant proposal") at the 2010 JMIH. A panel of experts was assembled that included the following people: Robert Espinoza, Karen Warkentin, Al Savitzky, Rafael de Sá, Dawn Wilson, and Henry Mushinsky.

Mike Jorgensen and Vinny Farallo replaced Matt Venesky and Cari Hickerson as co-chairs of the Student Travel Awards Committee. In 2011, in an attempt to increase visibility, Silent Auction items were placed in the registration lobby at the JMIH. The winners of the Travel Awards were required to staff the display table throughout the meeting. US $733 was raised in 2010. An important goal this past year was to increase donations and diversify donors. To achieve this, Mike sent an email to approximately 20 distinguished herpetologists with a personal letter describing the Silent Auction and the Student Travel Awards and solicited herp-related donations. Mike and Vinny intend to solicit donations from herpetologists each year, but not to solicit a donation during consecutive years from the same individual(s). The Silent Auction and Travel Awards now have a Facebook page and applications for awards are being accepted from both graduate and undergraduate presenters.

The main addition to the SSAR website was the Standard English and Scientific Names page along with a SSAR Facebook group page. The new SSAR logo was posted, and updates to the homepage content were made. A subcommittee of the Long Range Planning Committee (Bob Hansen, Breck Bartholomew, Raul Diaz) has begun discussion of the design and functionality of the website, and a new website should be in the works this year.

Coordinator's Reports.—Election Officer, Dan Noble, reported that most ballots were submitted electronically and the following individuals were elected in 2010:

President-Elect – Robert Aldridge
Treasurer – Kirsten Nicholson
Secretary – Marion Preest
Board Members (*Regular*) – Tiffany Doan, Carol Spencer
Board Member (*Conservation*) – Jennifer Pramuk
Board Member (*At Large*) – Travis LaDuc

In 2010, the SSAR/HL Live Auction featured items from the Roger Conant collection. Auctioneers for 2010 were John Moriarty and Frank Burbrink. The Live Auction Committee (Greg Watkins-Colwell, Coordinator) discussed the involvement of HL in the running of the auction and ways to improve the collaboration. The live auction made US $4,107 which was split 50-50 with HL. Additionally, the Roger Conant portion of the auction was for SSAR only, and brought an additional US $1,706 for a total of US $3,759.50. The 2011 Live Auction will consist entirely of materials from Ernie Liner and proceeds will be split among SSAR, ASIH, and HL. The Board approved a request to donate a free membership to be given away at the auction.

Al Savitzky, SSAR representative to AIBS and BioOne, reported that AIBS continues to serve as an effective umbrella organization for societies concerned with organismal and environmental biology. AIBS is deeply involved in a strategic planning process to evaluate its own role in the biological community, its unique contributions as an umbrella organization, and the value of its various activities and services. In recent years, two of those services have emerged as especially important elements of the AIBS program: public policy and education. AIBS is facing many of the same challenges as its member organizations, including declining individual membership and rising costs of operations and meetings, and has taken a number of steps to reduce its costs.

BioOne is a nonprofit electronic publishing consortium that serves many society publishers of journals in organismal biology and

ecology, as well as a few other fields. Al attended the annual BioOne Publishers and Partners Meeting in 2011. This year marks the 10th anniversary of the launch of the first BioOne collection, and during this time, BioOne has returned US $13.5 million to its society publishers. Over the 10-year period, the cost of BioOne to libraries has increased only 9.2%, whereas the Consumer Price Index has increased 23.5%. Such cost containment is consistent with BioOne's role as a collaboration between scientific society publishers and academic libraries.

Al reported that those at the annual meeting heard from a number of speakers, including one who noted a trend among university presses nationwide to publish more works by their own campus authors rather than by off-campus authors, and another who likened the support of open access scientific journals to the support of lighthouses in 19th Century Great Britain, where dues were assessed to shipping companies based on the size of the ships. BioOne is considering a pilot experiment in which libraries are assessed an "open access sustainability surcharge" to support OA content. Finally, Al made his annual inquiry about the prognosis for continuing print publication of JMIH society journals. As expected, more journals are now pursuing online-only or online-primary options. It seems that online-only as the basic membership benefit, with optional print-on-demand, is likely to emerge as the most common model, probably within the next few years. With declining membership among many organismal societies (SSAR is a rare exception), the publication of archival quality print journals will encounter a negative economy of scale, rendering the publication of archival print journals unsustainable. Few societies are planning yet for that eventuality. Al drew the Board's attention to the potential royalties that could be made if *Herp. Review* was available through BioOne. Breck recalled that a number of years ago BioOne was approached about *Herp. Review*. However, they were not interested because they viewed this publication as a news journal. Al thought that it was worth going back to BioOne and asking them again.

This year, SSAR Symposium Coordinator, Richard Durtsche, received two proposals. The first proposal, "Rethinking Normal: Moving from Theory to Action in the Face of Invasive Species and Global Change," was submitted by Joseph Mendelson III as lead organizer, with James P. Collins, Michael E. Dorcas, Karen R. Lips, Priya Nanjappa as co-chairs. The goal of this symposium is to move the discussion of invasive species (both invasive herpetofauna and those species that affect native herpetofauna) beyond just reports of exotic species and the ecological changes they cause, and into the realm of "The New Normal." Participants will discuss how globalization and invasive species, including emerging infectious diseases, are affecting the concepts, principles, and ethics related to rapidly changing ecosystems. The second proposal, "Technology and Innovation in Herpetology and Ichthyology Collections" was submitted by Greg Watkins-Colwell and Mark Sabaj Perez. The organizers' goal is to provide a symposium that is dedicated to collections by providing a platform for introducing researchers to new issues relevant to collections and also providing an environment where recent collection-relevant findings may be shared. Both symposium proposals were sent out for external review (two reviewers each). The reviews and proposals were submitted to the SSAR Board for consideration of sponsorship.

New Business.—Several recommendations were received from the LRPC (Kraig Adler, Chair).

1) *A recommendation to increase membership dues and institutional subscriptions for 2012*: SSAR has not increased dues in several years. The proposed increases result in dues that are not out of line with those of our sister societies. Kraig remarked that we need to increase our revenue stream, not just reduce costs. Our profit margin is very small (or non-existent) for some categories of membership, e.g., student memberships are currently US $35/yr and the mailing costs *alone* for journals to international students annually are US $31.44! The LRPC thinks that increases are warranted in virtually all categories of memberships in order to cover the costs of changes in format in our signature journals, a professional redesign of our website, launching a highly-effective membership campaign, and many other enhanced member services (e.g., increases in the Student Travel Awards budget). In addition to recommending dues increases, the LRPC also recommended formation of a new category (Regular, > 70 yrs of age) at a rate lower than that of a Regular membership. The Board discussed the proposed dues increases and the possibility of some members and institutions dropping their memberships in the light of these increases. Although we have had some institutions drop subscriptions that provide paper copies of our journals in favor of cheaper electronic access, the difference in dues is made up for in royalties from BioOne. Joe Mendelson suggested that student and zoo memberships should be equal. Breck expressed concern that the "shock" of moving from a student membership to a regular membership may lead to some individuals not renewing their memberships. The Board realizes that offering an electronic-only option will happen in the near future. The net effect on our finances is difficult to predict (how will lower dues be balanced by reduced printing and mailing costs?). Some changes to the proposed dues scheme and the effect on the bottom line were discussed and the Board approved the following changes effective January 2012:

- Regular – increase from $70 to $95
- Regular, seniors over 70 (new category) - $50
- Family – increase from $85 to $105
- Sustaining – increase from $100 to $125

PHOTO BY M. PREEST

Fig. 11.

Fig. 12.

- Student – increase from $35 to $45
- Zoo – increase from $35 to $45
- *Herp. Review*-only – increase from $25 to $50
- Institutional, *Herp. Review*-only – increase from $50 to $75
- Institutional, *Herp. Review* and *J. Herp.* – increase from $140 to $195

2) *A recommendation to reject a proposal from Allen Press to co-publish Journal of Herpetology*: In February, President Mendelson referred to the Board a 37-page proposal from Allen Press (AP), which resulted from prior contacts by AP with the co-editors of *J. Herp.*, Gad Perry and Erin Muths. AP proposed assuming much greater responsibility for *J. Herp.* including storing the journals, billing for page charges, setting of market rates, etc. In effect, AP would become the publisher of *J. Herp.* and SSAR responsible only for its content. The LRPC had several rounds of comments and responses. Most members found the proposal unacceptable on several grounds, both philosophical as well as material. For example, some could not see SSAR giving up control of its own journal to this degree. Others were persuaded by SSAR's earlier experience with AP when they took over membership management services, which turned out to have numerous hidden charges and ultimately a cost that was unsustainable for the society. Some pointed out that, if AP collected all page charges, then the editors would not be able to waive these costs for students or authors in developing countries, as they do now, thus reducing the coverage and attractiveness of *J. Herp.* as an international journal. Ultimately, three questions were posed to the LRPC: 1) Accept proposal as is; 2) Send questions to AP to resolve issues; and 3) Decline AP's proposal. Nine votes were received to decline the proposal, two votes to send questions to AP, and there was one abstention. The LRPC recommends that the Board decline AP's proposal. However, from the committee's discussion there are certain specific elements of the proposal that, on further investigation, we may wish to adopt. For example, the ability for the editors to store large data appendices electronically at AP would save much space (and cost) in *J. Herp.* Thus, a specific proposal could be entertained for such a service on a simple fee basis.

Discussion by the Board focused on these additional services. Secretary Preest recalled that SSAR received a proposal from Steve Godley two years ago offering to make appendices to papers published in our journals available on the website. These appendices could include audio and video files, photographs, databases, etc. Raul Diaz indicated that this is something we can do ourselves and do not have to involve Allen Press. The Board voted to decline the proposal from Allen Press as written.

3) *A recommendation against SSAR adopting Contemporary Herpetology*: In February, immediate Past-President Crother asked the LRPC to consider the possibility of adopting the existing open-access herp journal, *Contemporary Herpetology* (CH). Because there is no print version, the relative costs are low and it has the advantage of being able to include color video clips. On consideration, however, the LRPC decided against recommending SSAR adoption. The reasons were varied, but include these: SSAR already sponsors seven different publication series; *CH* would be an additional drain on society resources and, especially, on the small cadre of capable editors needed to staff our many existing series; and the advantages of *CH* could be incorporated into existing SSAR serials (for example, if the society's web page is to be expanded, video clips supporting articles in *J. Herp.*, *Herp. Review*, and other SSAR publications could be posted there). The Board supported the recommendation of the LRPC. Because *CH* has several attractive features, like the ability to post video clips, they referred this matter to the LRPC's website subcommittee to see if there are features that could be adopted for the benefit of the herpetological community.

The Co-Editors of *Journal of Herpetology* brought six issues to the attention of the Board.

1) *Difficulties in obtaining qualified Associate Editors and reviewers*: Gad and Erin reported that this remains the biggest challenge to a more rapid manuscript handling process. Many leading journals provide AEs some sort of recognition for their services. The suggestion last year to provide AEs free membership was one attempt to address this problem, however this was rejected by the Board. Gad and Erin requested that the Board reconsider this matter. Joe suggested that the co-Editors expand their Editorial Board and use them to help review manuscripts. For example, when individuals agree to be added to the Editorial Board, they must also agree to review up to 15 manuscripts per year. There was some discussion of the use of "tokens" to reward prompt reviewers and of using graduate students to help with reviews. An op-ed piece from the President could be used to remind members of the importance of this service to the continued quality of our journals. An online check box could be provided for members to indicate that they are willing to serve as reviewers when they renew their membership. The Board rejected the proposal to provide Associate Editors with free memberships, but it was agreed that some sort of gesture might be appropriate. The co-Editors were asked to consider this matter further.

2) *Page charges*: The Editors submitted a proposal regarding page charges as requested by the Board in 2010. According to this policy the Editors would retain the ability to waive page charges in special circumstances. There was some concern expressed that making page charges mandatory might hold up publication, however the Editors did not view this as a problem. The Board requested that Gad and Erin consider policies being used by the Editors of *Copeia*

and *Herpetologica* and develop a coherent page charge policy that includes the use of color.

3) *Preparing for e-publishing*: Gad and Erin noted that journals are increasingly going wholly or optionally digital and that *J. Herp.* needs to be prepared for such a move. They acknowledged that the LRPC is considering this issue and support providing a digital-only subscription option.

4) *Second language abstracts*: International journals often offer the option of a second language abstract and Gad and Erin would like to do the same. Allen Press can handle a variety of languages, although Spanish and Portuguese are expected to predominate. Gad and Erin foresee the authors providing the abstract upon submission, and an independent reader confirming that the content indeed matches the English-language abstract upon acceptance. The Department of Classical & Modern Languages & Literatures at Texas Tech is offering to provide this service for $15/manuscript. The Board viewed this as an important and long overdue concept. There was discussion of the use of SSAR members to review abstracts. Robin Andrews suggested that authors provide JPEG (or other) files of abstracts in the case of languages Allen Press is unable to typeset. The Board voted to approve offering second language abstracts and the request for a budget to cover associated costs.

5) *Editorial office expenses*: In the past, institutions for which editors have worked have provided many services for free, e.g., phone service, mail service, occasional office services, and an editorial assistant. With budget cuts looming, Texas Tech University has indicated its desire to have SSAR assume those costs. The Board voted to assume these costs if/when necessary.

6) *Co-publishing*: Following inquiries about additional services that Allen Press provides to *Herpetologica* but not *J. Herp.*, Gad and Erin learned that The Herpetologists' League has a different kind of contract with AP than does SSAR. They therefore asked AP to provide SSAR with a similar offer. This offer was forwarded to the Board and Long Range Planning Committee (LRPC) for increased overview and in-depth assessment. Gad and Erin appreciate the job that the LRPC did in exploring the ramifications and agree with some of the concerns that have been identified. However, they asked the Board to overrule the recommendation of the LRPC. As noted above, the Board voted to adopt the recommendation of the LRPC and decline the proposal from Allen Press as written.

Henry Mushinsky presented a report from an *ad hoc* committee on increasing JMIH society interactions. Included in this report were suggestions to form a JMIH Conservation Committee, to have greater co-sponsorship of symposia that would be less taxonomically based and more problem-oriented or topically based, to develop a joint JMIH Society webpage, to enter into joint negotiations with publishers, and to form an umbrella society that would, for example, take control of membership tracking and treasurer duties. There was no discussion of this report, as it will be considered by the LRPC later this year, before coming to the Board.

Brian Crother developed a policy on complimentary life membership and receipt of *gratis* copies of SSAR publications. The Board approved the recommendation to provide an Honorary Life Membership to individuals who donate $\geq$ 10 times the current cost of a life membership. It also approved the recommendation that those listed on the SSAR letterhead (i.e., officers and editors) be provided with *gratis* copies of society publications. There was discussion of giving "gift certificates" valid towards purchase of SSAR publications to Associate Editors of our journals. This suggestion was tabled.

There was discussion of what to do with SSAR's share of the proceeds of the Ernie Liner Auction. An Ernie Liner Endowment will be set up to support up-and-coming herpetologists. Further discussion will occur once the endowment is in place.

Once again, the Board discussed a name for the new Student Poster Competition. Roger Conant's name was suggested. Kraig offered to consult Roger's will to determine if this is appropriate. Discussion followed the Board meeting and it was suggested we name the Grants in Herpetology program after Roger. The Board later voted unanimously to support this proposal and we are pleased to announce the Roger Conant Grants in Herpetology Program.

Copyright issues and electronic access to articles published in *Herp. Review* and *J. Herp.* were discussed. Free access to these articles affects royalties we receive from JSTOR and BioOne. SSAR needs to develop and enforce a policy regarding copyright issues. Breck, with assistance from Kirsten and Editors Hansen, Perry, and Muths will develop such a policy and the Secretary will distribute this to the Board for discussion and a vote. A copy of the policy will be displayed on the website and included in print journals once finalized.

The Herpetology Education Committee submitted two proposals for the Board to consider. The first was a proposal that, in all cases where appropriate (e.g., in Annual Meeting information), "students" or "graduate students" be substituted by "undergraduate and graduate students." The Board approved this proposal. The second was a proposal for a new program that will cover single-day meeting registration fees for a pre-baccalaureate student (plus accompanying person if appropriate). There was discussion of how such individuals would be identified and selected, e.g., selected by a random drawing of names. A suggestion was made that prospective students be identified by local herpetologists, and applicants submit essays to members of the HEC, who will then select a winner. The Board approved this proposal.

Ann Paterson summarized the many activities of the Membership Committee, focusing particularly on the results of an extensive survey they administered recently. The importance of the Society website to the activities of this committee was recognized, and Ann was added to the LRPC website subcommittee.

The Board voted to donate its share of the proceeds of the 2012 Live Auction to the WCH minus associated costs. SSAR would appreciate an acknowledgment from WCH of this donation.

An enquiry was received from Josh Kapfer regarding increasing the number of GIH Awards. Gad Perry suggested that awards could be split between US and non-US members of SSAR. The Board was in favor of increasing the number of awards, but upon review of the budget, decided that this was not the year to increase the GIH budget. They agreed to consider this request in the future.

A balanced budget for 2011 of US $394,800 was approved by the Board and the meeting was adjourned at 1525 hrs (Fig. 12).

LRPC Meeting

An open meeting of the Long Range Planning Committee (LRPC) occurred on July 9th. LRPC Chair, Kraig Adler, called the meeting to order. Approximately 30 members of SSAR were in attendance. Kraig distributed an agenda and introduced members of the LRPC and other officers present. Four topics were the focus of discussion: future meetings (specifically venues and programs), the SSAR website, electronic-only memberships, and SSAR as an international society. Kraig began with a brief history of the annual meetings of SSAR. Over the years, annual meetings have consisted of SSAR-only, SSAR + HL, SSAR + HL + ASIH, and SSAR as part of JMIH. Herpetologist-only meetings are smaller than those including ichthyologists and might permit meeting on a university campus (rather than at a hotel or large conference center), something that younger members of SSAR will not have experienced. A question was raised about why SSAR

stopped meeting on campuses; the response was that the change was made for convenience and because it was getting difficult to find individuals willing to put the effort into organizing meetings. Someone pointed out that universities don't "reward" or encourage the effort involved in hosting a university-based meeting. K-State's involvement means that meetings are less work for the local committee, but this also reduces valuable input from that committee. Breck Bartholomew voiced his opinion that, unless we can find committed local committees, we needed to stick with the JMIH arrangement. Dawn Wilson suggested that mistakes in planning are more likely with local committees "starting from scratch every year" rather than having continuity with K-State. Having a template that gets refined and passed on each year would help with this problem. Mo Donnelly pointed out that the JMIH had received an offer from the University of New Mexico for the 2013 meeting but, because of university regulations, this would need to be a dry meeting. Someone suggested that the costs of university-based meetings were likely to be substantially higher than we remember from past meetings, e.g., we would not receive complimentary rooms as we do with hotels (assuming we meet our room block). The meeting would not necessarily have to be held at a university, i.e., a smaller herps-only meeting could be held at a conference facility.

Discussion then turned to SSAR's web presence. A website subcommittee (Bob Hansen, Chair, Breck Bartholomew, Raul Diaz) was formed recently (Ann Paterson was added to this committee at the Board Meeting). Bob briefly reviewed the history of the Society's website and indicated that we are ready to start with a "clean slate." Raul Diaz projected websites of other organizations on a screen and showed us sites of increasing complexity. We want the site to inform members and the public about the Society and also about the field of herpetology. The new SSAR website needs to be able to accommodate membership functions (complementing the ZenScientist site), be a dynamic site that plays a large role in meeting the needs of our members, permit downloading of SSAR publications, provide links to other herp sites, etc. There were suggestions of President's blogs and posting of teaching modules. There was some discussion of member-only versus public access and of peer-reviewed Wiki forums within the website. These would only be available to SSAR members to write/edit, and work on the Wiki pages would not be anonymous.

The following suggestions were made: that we provide pictures of officers, editors, and committee chairs on the webpage, that we have a mentoring program available through the website, that we provide information about keeping captive animals, that we post herp-related advertisements (similar to those currently in *Herp. Review*) on the website, that we post downloadable photos, teaching modules, lectures, membership directory (with rules as to use and the ability to unsubscribe), access to articles, videos of President's Travelogues and Plenary Sessions, videos of field experiences, videos of presentations by Seibert Award winners, videos of Student Poster Award winners, etc.

Concern was expressed about the amount of work all of this would entail for our webmaster (currently Raul). If we adopted an open-source platform such as Drupal, it would be possible for others (officers, editors) to update relevant parts of the website. Having this succeed would require multiple volunteers being responsible and diligent.

There was brief discussion of electronic-only membership in SSAR. Kraig thinks we will have an electronic-only membership option available within a year. A poll was taken of those in the room under 40 yrs of age. Of the 15 individuals present, seven indicated they would select an electronic-only option, three would select print-only option and five indicated they would choose an electronic + print option. A suggestion was made that we ask the same question of the entire student membership

Finally, there was discussion of the role of SSAR as an international society. Despite the fact that most members and officers of SSAR are in North America and that most of the meetings are held in North America, SSAR very much considers itself an international society. Kraig asked whether there was interest in more international venues for meetings—there was! Kris Kaiser thought that holding meetings in regions other than North America sent a very important message to non-US members of SSAR, many of whom are financially unable to attend meetings in North America. There was talk of setting up an endowment for non-US student members of SSAR to attend meetings in North America. SSAR could think about broadcasting sessions at meetings on the website to non-US members and posting abstracts in languages other than English on the website. This would make them accessible to non-English speaking members as well as freeing up print space in *J. Herp.*

SSAR Business Meeting

Later that same day, the Annual SSAR Business Meeting was called to order by President Mendelson (1805 h on July 10th). Attendance was high—well over 100 members of SSAR were present. Joe commented on and held up for display, certificates of appreciation from SSAR to Bob Powell, Andy Price, and George Rabb. Robert Powell was Index Editor for *Catalogue of American Amphibians and Reptiles* (*CAAR*) from 1988–1991 and Editor-in-Chief from 1991–2004. Andrew H. Price has served as Section Editor for Sauria and Amphisbaenia for *CAAR* from 1987–present and as Editor-in-Chief from 2005–present. As Editors, Bob and Andy served *CAAR* from account no. 506 in 1991 through account no. 900 (appearing later this year). We greatly appreciate the dedication that Bob and Andy have shown to *CAAR* and SSAR. George B. Rabb, Director Emeritus of Brookfield Zoo, was presented with a life-time achievement award to recognize his career commitment to conservation of wildlife globally, with special reference to his leadership in implementing the IUCN Species Survival Commission, the Declining Amphibian Populations Taskforce, the Amphibian Ark, and most recently the Amphibian Survival Alliance. SSAR is proud to count George Rabb among our membership.

Officers, Editors, and Committee Chairs who were at the Business Meeting introduced themselves to the other attendees and gave brief summaries of their Annual Reports and relevant information from the Board Meeting. Bob Hansen requested that those interested in reviewing material for *Herp. Review* (students especially) contact him. Gad Perry echoed that sentiment and asked that, if you are contacted to review a manuscript and are unable to do so, you notify the editors of *J. Herp.* promptly. Winners of the 2011 Seibert Awards were announced (Fig. 13). The Society was asked to endorse a resolution from the Amphibian Survival Alliance to support amphibian conservation. The Board later voted electronically and unanimously supported this resolution. A proposal was received to unify the Conservation Committees of the four JMIH Societies (AES, ASIH, HL, SSAR). A committee representing all societies (5 members from SSAR, including one student) will be formed to investigate this proposal over the next year. The meeting was adjourned at 1935 h.

— Respectfully submitted by Marion Preest, SSAR Secretary

NEW BOOK FROM S.S.A.R.

HERPETOFAUNA OF ARMENIA AND NAGORNO-KARABAKH

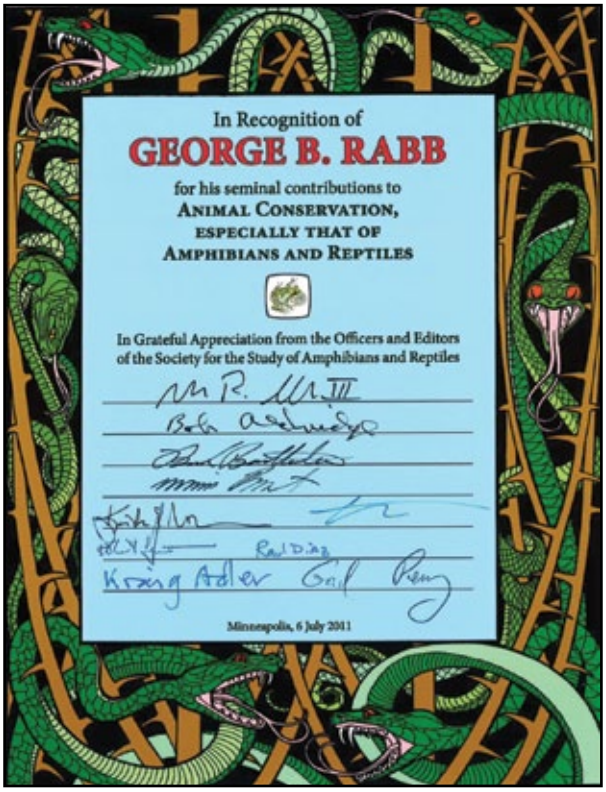
by Marine S. Arakelyan, Felix D. Danielyan, Claudia Corti, Roberto Sindaco, and Alan E. Leviton

Paleontological notes by David Vasilyan

THIS VOLUME COVERS THE HERPETOFAUNA OF ARMENIA and its neighboring republic of Nagorno-Karabakh, situated in the mountainous South Caucasus between the Black and Caspian seas, and surrounded by Georgia, Azerbaijan, Iran, and Turkey. The geographic position of these republics, the complicated regional geological structure, and zonation contribute to many types of ecosystems and biodiversity richness. Located at the crossroads between Asia and Europe, the Caucasus has been identified by the World Wildlife Fund for Nature as a "Global 200 Ecoregion" and by Conservation International as one of the world's 25 most biologically rich global "hotspots." The herpetofauna of Armenia and Nagorno-Karabakh includes 59 species, more than half of which are threatened, and of which 11 are endemic to the Armenian Plateau and Lesser Caucasus.

The book covers 17 families: 4 of amphibians, including both salamanders and frogs: Salamandridae (1 genus: 1 species), Pelobatidae (1:1), Bufonidae (1:1), Hylidae (1:2), Ranidae (2:2); 12 families of reptiles, including 3 families of turtles: Emydidae (1:1), Bataguridae (1:1), Testudinidae (1:1); 5 families of lizards: Gekkonidae (1:1), Agamidae (3:3), Anguidae (2:2), Lacertidae (5:17), Scincidae (3:4); and 4 families of snakes: Typhlopidae (1:1), Boidae (1:1), Colubridae (12:16), and Viperidae (3:4). Among the lizards, the lacertid genus *Darevskia* is of particular interest because it was among these lizards and in Armenia that Ilya Darevsky, to whose memory this volume is dedicated, first discovered parthenogenesis in reptiles.

There is an historical review of herpetological studies in the region (beginning with expeditions by czarist Russia in 1835) and an extensive key to species (with 72 interpretive photographs). **Each species account includes:** synonymy, type locality, taxonomic notes, distribution, habitat, size, karyotype, conservation status, and major references. There is an extensive bibliography and a comprehensive index. The color plates contain 151 photographs of animals and their habitats plus 60 colored maps with individual localities plotted.



The team of authors consists of two Armenians (Marine Arakelyan and Felix Danielyan) and two Italians (Claudia Corti and Roberto Sindaco) who have conducted all of the field investigations, much of it spanning nearly two decades, and an American (Alan Leviton) who specializes on Asian herpetology.

Specifications: *186 pages, 7 × 10 inches, 60 color maps, 72 figures, 4 tables, 151 color photographs, clothbound. ISBN 978–0–916984–84–7.* ***To be issued December 2011.***

PRICES: **SSAR members US$35 before April 2012; Institutions, non-members US$40.** ***SHIPPING:*** **USA address, add US$5; non-USA, at cost.**

Send orders to: Breck Bartholomew, SSAR Publications Secretary, P. O. Box 58517, Salt Lake City, Utah 84158–0517, USA (*telephone*: area code 801, 562–2660; *e-mail*: ssar@herplit.com). Make checks payable to "SSAR." Overseas customers may make payment in USA funds using a draft drawn on American banks or by International Money Order. All persons may charge to MasterCard, American Express, Discover Card, or VISA (please provide account number and expiration date). SSAR membership details and a complete list of all Society publications can be obtained on request to the Publications Secretary (address above). For details, check the Society's website at www.ssarherps.org.

Lifetime Achievement Award for George Rabb

At the 2011 SSAR Board Meeting, George B. Rabb, Director Emeritus of Brookfield Zoo, was presented with a lifetime achievement award to recognize his career commitment to conservation of wildlife globally, with special reference to his leadership in implementing the IUCN Species Survival Commission, the Declining Amphibian Populations Taskforce, the Amphibian Ark, and most recently The Amphibian Survival Alliance. SSAR is proud to count George Rabb among our membership.

Seibert Award Winners for 2011 Announced

The 20th annual Seibert Awards were presented at the 54th Annual Meeting of the SSAR in Minneapolis, Minnesota, 6–11 July 2011. These awards are named in honor of Henri C. Seibert, an early and tireless supporter of SSAR (having served as an officer for over 20 years). In recognition of outstanding student presentations at the annual meeting, a single award was given in each of the following categories: Evolution/Systematics (9 presentations), Ecology (12 presentations), Physiology/Morphology (6 presentations) and Conservation (8 presentations). All awardees will receive a check for US $200 and a book from Chuck Crumly at University of California Press.

The Winners –Systematics/Evolution: **Daniel Scantlebury** (University of Rochester), "Patterns of Adaptive Radiation in West Indian Dwarf Geckos (Sphaerodactylidae: *Sphaerodactylus*)." Ecology: **James Paterson**, Brad Steinberg, and Jacqueline Litzgus (Laurentian University), "Generally Specialized or Especially General? Habitat Selection by Snapping Turtles (*Chelydra serpentina*)." Conservation: **Jeanine Refsnider** and Fredric Janzen (Iowa State University), "Nest-site Choice in Response to Climate Change and Effects on Offspring Performance in a Turtle with Temperature-dependent Sex Determination." Physiology/Morphology: **Angela Rivera** (Clemson University), "Evolution of Flapping in Turtles: A Comparative Examination of Forelimb Kinematics and Muscle Function across Three Lineages (Trionychidae, Carettochelyidae, Cheloniidae)."

The judges were Cathy Bevier (Colby College), Rafe Brown (University of Kansas), Tiffany Doane (Central Connecticut State University), Nirvana Filoramo (Wesleyan University), Mac Given (Neumann College), Noah Gordon (University of Evansville), Eric Juterbock (The Ohio State University), and Patrick Owen (University of Cincinnati).

SSAR Student Poster Awards, 2011

Because of the continuing success of the SSAR Seibert Award competition for best student presentation at the annual meeting, SSAR decided to expand its annual award offerings to recognize student poster entries as well. President Mendelson suggested the creation of the SSAR Student Poster Award to the Board of Directors during the 2010 meeting and it met with unanimous support from the Board. 2011 was the inaugural year for the award with 20 entries in three categories. This year's judges were Tiffany Doan (chair, Central Connecticut State University), Marina Gerson (California State University, Stanislaus), Carol Spencer (University of California, Berkeley), Greg Watkins-Colwell (Yale Peabody Museum), Matthew Gifford (University of Arkansas at Little Rock), Dana Drake (University of Missouri), and John Roe (University of North Carolina).

The Winners.—Evolution, Genetics, & Systematics: **Anthony Geneva** (University of Rochester), "A Multi-locus Molecular Phylogeny of Distichoid Anoles." Ecology, Natural History, Distribution, & Behavior: **Beth Pettitt** (University of Minnesota), "Oviposition and Tadpole-rearing Site Selection of a Phytotelm-breeding Frog, *Anomaloglossus beebei*." Physiology & Morphology: **Mingna Zhuang** (University of California, Berkeley), "Comparative Gliding Performance of *Anolis carolinensis* and *Anolis sagrei*."

NEWSNOTES

Jones-Lovich Grant in Southwestern Herpetology

Thanks to the generosity of Larry Jones and Rob Lovich, 100% of the proceeds from the sale of their book, *Lizards of the American Southwest* (2009, Rio Nuevo Press), goes to support herpetological graduate field research in the American Southwest, including the southwestern United States and northwestern Mexico. An award (US $1000) will be presented to one winner. This research can focus on any aspect of amphibian or reptile biology, including behavior, conservation, ecology, physiology, or morphology and systematics. See The Herpetologists' League web site for application form, complete rules and details, along with the cover page at: http://www.herpetologistsleague.org/dox/joneslovichgrant.pdf. Entries must be received by 5:00 pm Pacific Time on 9 January 2012.

New Smithsonian Graduate and Professional Course—Species Monitoring and Conservation: Amphibians

The Smithsonian-Mason Global Conservation Studies Program will offer "Species Monitoring and Conservation: Amphibians" at the Smithsonian Conservation Biology Institute, Front Royal, Virginia, USA from 26 March to 6 April 2012. Visit http://conservationtraining.si.edu or contact SCBItraining@si.edu for more information about this course and additional upcoming courses of potential interests to herpetologists.

MEETINGS

Exploring the Secret Lives of the World's Most Studied Snake Group: A Second *Biology of the Rattlesnakes Symposium*

As the lightning of a monsoonal thunderstorm lit up the night sky, the second *Biology of the Rattlesnakes Symposium* got underway on the evening of 23 July 2011, at the Tucson, Arizona, Marriot University Park hotel. Hotel employees marveled at the throng of rattlesnake devotees, some 240 strong (Fig. 1), that began the registration process in a room filled with vendors displaying ophidiophilic T-shirts, hats, books, artwork, snake hooks, and radiotelemetry equipment—not to mention the numerous live rattlesnakes on exhibit.

PHOTO BY BILL LOVE

FIG. 1. Participants at the Second Biology of the Rattlesnakes Symposium, July 2011, Tucson, Arizona.

The formal symposia commenced the next morning with a stellar keynote address by Harry Greene of Cornell University, New York: "*Fifty years after Klauber: What's it Like to be a Rattlesnake?*" Harry set a much-appreciated tone with his appeal to portray rattlesnakes in the best possible light (deemphasizing their danger) while articulating their capacity to "think" and solve survival-related problems. Upwards of 65 oral and 14 poster presentations then followed over the three-day period, which included one all-day session at the beautiful facilities of the Arizona-Sonoran Desert Museum. The majority of papers focused on field ecology research, though studies of behavior, morphology, physiology, systematics, venom, toxicology, and snakebite were also represented. Two photographers, Manny Rubio and Bill Love, showcased their beautiful images of snakes and snake lovers.

The formal meetings concluded with a banquet featuring Jonathan Campbell of the University of Texas at Arlington, who described his fascinating career work on rattlesnakes and other venomous snakes in Mexico and Mesoamerica. The banquet also included a lively auction to benefit a graduate student research fund. Many participants attended the barbecue the next day at the Chiricahua Desert Museum in Rodeo, New Mexico, with proceeds also benefiting the graduate student research fund.

This taxon-specific meeting continued the tradition of prior symposia devoted to venomous snakes. According to the 80 respondents of an online survey, fewer than half (only 35%) attended the first *Biology of the Rattlesnakes Symposium* at Loma Linda University, California, in 2005. Only a smattering (up to 8%) previously attended the *Biology of the Pitvipers Symposium* (1989), the *Biology of the Vipers Symposia* (2000, 2007, 2010), or the *Eastern Massasauga Symposia* (1992, 1998, 2005). Clearly, many of the participants at the Tucson meeting represented "new blood," enthralled by the latest research findings on the world's most studied group of snakes (Beaman and Hayes 2008). University faculty, staff, and students comprised the majority of participants, but those of other diverse professions attended as well, including government, zoo, museum, and healthcare employees. Although many individuals enjoyed herping in the nearby area, particularly during the night hours, socializing with other herpetologists rated as one of the favorite aspects of the symposium.

The popularity of this symposium assured a future encore. According to the survey, participants favored the idea of meeting every three years, preferably in the southwestern U.S. during the late summer. However, Mexico was deemed feasible by many as a future meeting locale, with Central America and South America less desirable.

Overall, the participants gave the meetings high praise. The organizers, Bob and Sheri Ashley of Ecouniverse and the Chiricahua Desert Museum, Rodeo, New Mexico, assisted by Lori King Painter, also of New Mexico, did an outstanding job. Generous donations kept the cost of the symposium appreciably affordable to many. The primary sponsors included BTG (marketer of CroFab antivenom for humans), Red Rock Biologics (marketer of rattlesnake vaccines for dogs and horses), Rare Disease Therapeutics (distributor of Bioclon antivenoms for snakes and invertebrates), the Arizona-Sonora Desert Museum, and the Chiricahua Desert Museum.

A refereed volume similar to *The Biology of Rattlesnakes* (following the 2005 meeting) and those generated by prior symposia (*Biology of the Pitvipers, Biology of the Vipers*) will be published in due course.

Meetings Calendar

Meeting announcement information should be sent directly to the Editor (HerpReview@gmail.com) well in advance of the event.

12–13 January 2012—California-Nevada Amphibian Population Task Force Meeting, Placerville, California, USA. Information: bradford.david@epa.gov

14 January 2012—California Reptile and Amphibian Conservation and Management Forum, Placerville, California, USA. Information: Brian Todd (btodd@ucdavis.edu).

16–19 February 2012—"Connecting Efforts and Identifying Gaps in Southeastern Amphibian and Reptile Conservation." Southeastern Partners in Amphibian and Reptile Conservation (SE PARC) Annual Meeting, Fall Creek Falls State Park, Tennessee, USA. Information: SEPARC@SEPARC.org.

25–28 July 2012—35th International Herpetological Symposium, Hanover, Maryland, USA. Information: http://www.kingsnake.com/ihs/.

8–14 August 2012—World Congress of Herpetology 7, Vancouver, British Columbia, Canada (together with SSAR, HL, ASIH). Information: http://www.worldcongressofherpetology.org/

16–19 August 2012—10th Annual Symposium on the Conservation and Biology of Tortoises and Freshwater Turtles, Tucson, Arizona, USA. Co-hosted by the Turtle Survival Alliance and IUCN Tortoise and Freshwater Turtle Specialist Group. Information: http://www.turtlesurvival.org.

2–7 September 2012—4th International Zoological Congress (IZC), Mount Carmel Campus, University of Haifa, Haifa, Israel. To receive the first and subsequent meeting announcements, contact the organizers at: izc2012@sci.haifa.ac.il.

CURRENT RESEARCH

The purpose of Current Research is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, Joshua Hale or Ben Lowe; e-mail addresses may be found on the inside front cover.

A listing of current contents of various herpetological journals and other publications is available online. Go to: http://www.herplit.com and click on "Current Herpetological Contents."

Anolis Lizards Demonstrate Problem Solving

Cognitive ecology is the study of how functional explanations of behavior, such as those provided by behavioral ecology, can be integrated with an understanding of the underlying neural and physiological mechanisms. An important component of cognitive ecology is the study of behavioral flexibility. According to theoretical predictions, species that need to exploit a variety of resource types or habitats, or have a complex social structure are likely to show elevated levels of behavioral flexibility. As a consequence, study of behavioral flexibility has concentrated on birds and mammals, as they are traditionally thought to have these characteristics. In contrast, these attributes are not normally associated with ectothermic vertebrates, and as a consequence, they have been neglected in studies of behavioral flexibility. In order to begin to redress this imbalance, the authors of this paper have examined behavioral flexibility in the arboreal lizard *Anolis evermanii* from Puerto Rico. A range of tasks were designed to test cognitive abilities. First, lizards were presented with an opaque grey platform with two wells. Habituation to this experimental setup was conducted over three steps. First, a reward (freshly killed *Hermetia illucens* larvae) was placed in one of the wells, then a small, blue-colored disc was placed next to the well, and finally, this disc was used to half cover the well. For the first part of the experiment, this disc was fitted tightly over one well containing a reward. Of the six lizards (three males and three females) used, four successfully removed the disc to access the reward using one of two strategies, either biting the edge of the disc or using their snout as a lever to dislodge it. These four lizards were used in two subsequent experiments in which the second well was covered with a 'distracter' (either a yellow disc or a disc colored with blue and yellow concentric circles). Overwhelmingly, using both distracters, each of the four lizards was able to successfully choose the target without mistake. Finally, trials were conducted to test reversal learning by placing the reward under the blue and yellow disc. Two of the four lizards were able to demonstrate reversal learning, while the other two stopped responding due to lack of reinforcement. The ability of these lizards to solve a novel motor task using multiple strategies, associative and reversal learning, demonstrates sophisticated cognitive abilities, including behavioral flexibility. The authors highlight that as a group, *Anolis* lizards are known to exploit a range of different ecological conditions and exhibit complex behavior, attributes normally associated with behavioral flexibility. The authors do point out that this group's ability to display behavioral flexibility may have facilitated its ecological diversification. These findings do suggest that the cognitive abilities of ectothermic tetrapods are more developed than previously thought.

Impact of Small-scale Fisheries on Marine Turtles

The impact of industrial fisheries on non-target, 'bycatch' species has been well documented, and has been implicated as a key factor driving population extirpation in marine turtles. Recently, awareness has been growing that similar impacts could result from interactions with small-scale fisheries. Small-scale fisheries (SSF) are defined by smaller vessels with minimal levels of mechanization compared to industrial fisheries. Although bycatch by SSF may be less than industrial fisheries at the individual level, fleets may be extremely large, especially in developing countries. In this study, the authors examined the impact of SSF on marine turtles in Peru. Onboard and shore-based observers assessed bycatch levels of four different fisheries (bottom set nets, driftnets, and two longline fisheries) from three SSF ports in Peru from 2000 to 2007. In total, 264 fishing trips were observed, with 807 turtles captured, approximately 92% of which were released alive. Loggerhead Turtles made up 51.2% of this bycatch, Green Turtles 41.4%, Olive Ridley Turtles 3.2%, Leatherback Turtles 2.1%, and unidentified species 2.1%. From this survey effort, it was estimated that approximately 5900 sea turtles are captured annually from these three SSF ports alone. The authors estimate that there are greater than 100 SSF ports in Peru representing more than 950 vessels and 37,000 fishers and as a result, the impact of SSF on sea turtles in the region may be severe. The authors also discuss the use of marine turtles as important food sources for coastal communities, and how these issues should be considered when recommending management and conservation strategies.

Alfaro-Shigueto, J., J. C. Mangel, F. Bernedo, P. H. Dutton, J. A. Seminoff, and B. J. Godley. 2011. Small-scale fisheries of Peru: a major sink for marine turtles in the Pacific. Journal of Applied Ecology (*in press*). doi: 10.1111/j.1365-2664.2011.02040.x.

Seasnakes Shelter in Disused Seabird Burrows

Ecosystem engineers alter the physical environment to increase their own fitness, but in the process can benefit other species, by providing new habitats, increasing productivity of an area or enhancing the functioning of the local ecosystem. Burrowing species are one such example of ecosystem engineers providing habitat for sympatric species, however some burrowing species behaviorally exclude other sympatric species from using these burrows. In this study, the authors have examined the use of burrows created by the Wedge-tailed Shearwater (*Puffinus pacificus*), on New Caledonia in the Pacific Ocean. Two species of laticaudine seasnakes are abundant on New Caledonia: the primarily terrestrial Yellow-banded Sea Krait (*Laticauda saintgironsi*) and the more aquatic Blue-banded Sea Krait (*Laticauda laticaudata*). For this study, the authors used video cameras to inspect 102 burrows. It was found that *L. laticaudata* are restricted to burrows that are closer than 4 m to water's edge, while *L. saintgironsi* tended to utilize burrows further inland. Seasnakes and shearwaters were never observed in the same burrow, suggesting shearwaters actively defend these burrows. To examine burrow defense behavior more closely, model snakes were inserted into burrows, and the frequency of attack by adult shearwaters was recorded. In total, 165 model snakes were introduced into 55 burrows (three models per burrow: blue & black- and yellow & black-banded, to mimic *L. saintgironsi* and *L. laticaudata* respectively, and one all-black control model), eliciting 41 responses from resident shearwaters. In 34 cases, the model was attacked, on six occasions the resident bird stood or sat on the model and in one case the adult shearwater fled the nest. These experiments revealed that the likelihood that a bird would attack a model snake was unrelated to its color. The authors outlined the advantages of sheltering in burrows for seasnakes, including protection from predators, thermal benefits, and increased access to fresh water. This study provides an example of an ecosystem engineer acting both as a facilitator and a competitor of a sympatric species.

Effective Population Size Correlated with Breeding Pond Size in an Endangered Salamander

One of the fundamental goals of conservation biology is the maintenance of genetic diversity and population viability. Effective population size (N_e), essentially the number of individuals that will contribute genes equally to the following generation, is an important factor in maintaining genetic diversity, preventing inbreeding depression, and predicting the likelihood of population persistence. In this study the authors examined the correlation between breeding pond characteristics and effective population size in the endangered California Tiger Salamander, *Ambystoma californiense*. Microsatellite markers were used to assess effective population size as well as heterozygosity and allelic diversity. The area of each pond was calculated and each was classified as being either a hydrologically modified perennial pond or a naturally occurring vernal pond. Although no correlation was found between pond area and either heterozygosity or allelic diversity, there was a strong positive relationship between N_e and pond area, particularly for vernal ponds. The authors propose that this may be due to large vernal ponds drying out relatively slower than smaller ponds, and therefore suffering lower mortality. The relationship between N_e and pond size was logarithmic, which, according to the authors, suggests that there is an upper limit to N_e in large ponds. Despite the low effective population sizes in smaller ponds, there was no observable reduction in allelic diversity or heterozygosity, suggesting that these ponds are not experiencing the usual fitness costs associated with small populations such as bottlenecks and inbreeding depression. The authors suggest that understanding the relationships between N_e and habitat characteristics would be very important for wildlife managers designing comprehensive conservation plans.

Wang, I. J., J. R. Johnson, B. B. Johnson, and H. B. Shaffer. 2011. Effective population size is strongly correlated with breeding pond size in the endangered California tiger salamander, *Ambystoma californiense*. Conservation Genetics 12:911–920.

Relationships Between Body Size and Habitat in Turtles and Tortoises

Chelonians, the turtles and tortoises, display remarkable size variation, spanning almost four orders of magnitude. At one end of the scale are tiny terrestrial species like *Homopus signatus*, the 80 g Speckled Padloper Tortoise, and at the other, the gigantic marine turtles such as the 500 kg Leatherback (*Dermochelys coriacea*). Despite the remarkable size variation observed, understanding of the evolutionary basis for this variation remains poor. In this study, the authors tested the hypothesis of a correlation between habitat (freshwater, terrestrial, oceanic, and insular) and body size by evaluating the fit of different models of turtle body size evolution to a time-calibrated phylogeny including about 70% of extant chelonians and replete with estimated ancestral habitat states. The results of these analyses provided strong support for different optimal sizes in chelonians that occupy different habitats. In the best performing model, optimal body size for marine chelonians and those from oceanic islands was large (island optimum = 82.6 cm, marine optimum = 132.6 cm) relative to optimal size in freshwater and mainland species (freshwater optimum = 33.7 cm, mainland optimum = 24.18 cm). Traditionally, large optimal body size in oceanic island tortoises was thought to reflect a preadaptation for increased dispersal ability, necessary for initial colonization. The authors suggest that the retention of large body size for chelonians on oceanic islands reflects the low predation and unpredictable climatic conditions, such as drought or low resource availability, characteristic of islands. In addition, long distance travel between feeding sites may still be important for island turtles. The authors suggest that the relatively large body size of marine turtles might

also reflect an adaptation to long distance travel, as well as to cold conditions encountered during these journeys. The greater variety of potential niches in terrestrial and freshwater environments may ensure that the relationship between body size and habitat is more complex for chelonians in these habitats.

Jaffe, A. L., G. J. Slater, and M. E. Alfaro. 2011. The evolution of island gigantism and body size variation in tortoises and turtles. Biology Letters 7:558–561.

MicroRNA Analysis Used to Investigate Origin of Turtles

Despite a number of previous studies, the phylogenetic position of the turtles remains contentious. Some morphological analyses place turtles outside Diapsida, the clade that includes crocodiles, lizards, tuatara, and birds. Other morphological studies have placed turtles within Diapsida, close to the Lepidosauria (tuatara and lizards). Finally, although the majority of molecular studies do place turtles within Diapsida, they instead ally them most closely with Archosauria (crocodilians and birds). The authors highlight that the conflicting phylogenetic relationships inferred from these different analyses are just three different rooting hypotheses for a single, unrooted four-taxon tree (birds and crocodiles are always sister, which leaves three branches upon which the root can be placed). In this study, the authors examined a heretofore unevaluated molecular character type: microRNA (miRNA) genes. miRNAs are short (~22 base pair) RNA molecules that help determine the fate of messenger RNA molecules, and as new miRNAs are added to metazoan genomes infrequently over time and are rarely lost, they represent useful tools for shedding light on phylogenetic relationships. RNA was extracted from single individuals representing turtles (*Chysemys picta*), lizards (*Anolis carolinensis*), and crocodilians (*Alligator mississippiensis*). These were then compared to a number of previously published sequences, including mammals (platypus, opossum, and human), birds (Zebra Finch and chicken), and a frog. Maximum parsimony analysis was performed and Bremer support used to assess the support of each node. Results of this analysis unambiguously support a turtle and lizard clade, with these two groups sharing four unique miRNA gene families that are not observed in any other organism's genome. Further, no miRNAs are found in all diaspsids but not turtles, nor in turtles and archosaurs but not diapsids. The authors posit that these findings suggest that a number of morphological convergences and reversals have occurred within the reptile tree, and propose that the lepidosaur/turtle crown clade be called "Ankylopoda," meaning "fused foot."

Simultaneous Polyandry Provides Genetic Benefits to Offspring of African Tree Frog

Polyandry, multiple female matings within a single reproductive cycle, is widespread across a range of taxa. It may be driven by males forcing copulation. However, in some cases females gain direct material benefits, such as parental care or nutrient donations, or genetic benefits that indirectly increase female fitness. Hypotheses of the genetic benefits of polyandry fall into three main categories. First, females that mate with multiple males reduce their chance of mating with an inferior quality male. Second, females may increase their chances of mating with a genetically compatible male. Third, polyandrous females have more genetically diverse offspring, which may benefit females because genetically dissimilar offspring compete less for resources, or because genetic diversity increases the likelihood that some will be able to respond to novel selective conditions. In some species, the females engage in simultaneous polyandry, where one female mates with multiple males at the same time. For instance, up to 90% of female Gray Foam Nest Treefrogs (*Chiromantis xerampelina*; a southeast African species) mate with up to ten males simultaneously. Although this represents an extreme example of polyandry, the hypothesis that females are gaining genetic benefits from this reproductive strategy has not previously been evaluated. In this study, the authors compared the fitness of offspring produced by polyandrous and monandrous matings. Body size did not differ between females involved in monandrous and polyandrous matings and offspring of these two matings did not differ in age or size at metamorphosis. However, offspring from polyandrous matings had higher mean survival and a reduced variation in offspring survival. The authors suggest that these results implicate genetic factors as a possible mechanism favoring polyandrous matings. However, a series of breeding experiments controlling for maternal quality and possible paternal material effects needs to be carried out to definitively determine whether paternal sire effects, genetic compatibility, or offspring genetic diversity underlies the advantage of this reproductive mode.

Byrne, P. G., and M. J. Whiting. 2011. Effects of simultaneous polyandry on offspring fitness in an African tree frog. Behavioral Ecology 22:385–391.

Age Does Not Diminish Regenerative Capabilities in Newts

The regenerative capacity of newts is remarkable, encompassing both tissues and organs, as well as external limbs, tails, and eyes. This ability is particularly interesting for medical regeneration research, and as a consequence, newts have been studied in this context for over 200 years. Despite the long history of research, one persisting question remains: to what degree does age or repeated injury deplete a newt's ability to regenerate tissue? Previous studies have suggested that repeated

amputations still lead to regeneration, but occasionally with mistakes, such as missing bone structure. However, these studies may have lacked adequate controls. Further complicating these studies, newts generally do not thrive in captivity, and it is difficult to determine the age of wild caught individuals. In order to investigate the regenerative capacity of newts over time and repeated injury, the authors conducted a long term study in a captive population of Japanese Newts, *Cynops pyrrhogaster*. Newts were collected in 1994, and over the subsequent 16 years, eye lenses were removed from the same animals 18 times. Understanding regeneration of this specific tissue is of heightened interest, as lens loss is very rare in nature and therefore should not be under natural selection (lens regeneration in newts has also fascinated biologists for over a century). The 17th and 18th regenerated lenses were virtually identical structurally to the lenses removed from 14-year old adult newts with unaltered lenses. Further, quantitative PCR showed that gene expression patterns were very similar to those of the control group. These findings, which suggest that amphibian regeneration does not diminish with age or repeated injury, are contrary to traditional thought and are of great importance to medical regeneration research.

Some Opossums have Rapidly Evolved a Resistance to Viper Venom

"Evolutionary arms races" are situations in which two species (frequently predator and prey) have undergone marked evolution in the effort to keep up with each other. Despite being accepted as a common evolutionary scenario, no evolutionary arms race between a predator and a venomous prey species has been demonstrated with molecular data. The authors of this paper used molecular data to test the hypothesis that one New World opossum lineage within the family Didelphidae has evolved a resistance to the venom of one of their preferred prey items, pit vipers (Crotalinae). Previous work had established that one venom toxin, C-type Lectin-like Protein (CLP), targets platelets, the structures in charge of forming blood clots. Specifically, CLP attacks a membrane protein called the von Willebrand Factor (vWF). The authors accumulated DNA sequence data representing a stretch of the vWF known from previous studies to be particularly affected by CPL for a series of didelphid opossums (including both venom resistant and non-resistant species) and other mammals. They then employed rigorous, likelihood-based methods to evaluate two models of evolution: one dividing nucleotide site substitutions into two categories for all taxa (no selection and purifying selection; H_0) and one allowing for a third category (positive selection) for venom-resistant opossums (H_A). The authors also used a Bayesian method to identify nucleotide sites along the sequence that are under particularly strong positive selection in the viper-eating opossum lineage. These analyses revealed that the vWF protein of venom-resistant opossums has experienced an elevated rate of evolutionary change relative to other mammals. The likelihood test found the alternative model was a significantly better fit than the null model, and 10% of the nucleotide sites were found to be under strong positive selection in the ophiophagous opossums. One interesting discovery was that the enigmatic South American Water Opossum (*Chironectes minimus*), which is thought to specialize on fish and crustaceans and is the sister taxon to the established viper-eating opossums clade, was found to have the molecular signal of venom resistance. Whether this species exhibits a derived diet and evolved from a viper-eating ancestor or if it is a secret ophiophage remains to be determined. Finally, the authors point out that in theory, arms races where the prey is dangerous to the predator should result in the most rapid rate of character evolution, and therefore the assumption that snake venom evolved primarily for prey apprehension should be re-examined.

Daphnia magna as a Possible Control for Amphibian Chytrid Fungus

The chytrid fungus, *Batrachochytrium dendrobatidis* (*Bd*), is a nearly global concern with its negative impacts on amphibians well documented. Despite the extent of this crisis, the authors of this review paper (Woodhams et al. 2011) suggest that rescuing amphibian diversity in the face of *Bd* is an achievable aim. The authors examined different disease mitigation strategies, discussed the precedent for each strategy, and assessed their long-term potential. The authors suggest that sustainable conservation is dependent on long-term population persistence and co-evolution with the potentially lethal pathogens. As such, strategies should not rely exclusively on pathogen elimination or captive breeding, but also focus on reducing pathogenicity and host susceptibility in already infected populations. The authors propose population level treatments based on three steps: first, identify mechanisms that allow disease suppression in the population; second, the parameterization and testing of models of disease/host dynamics; and third, the trialing of adaptive management in field populations.

In line with the first of the three steps suggested by Woodhams et al. (2011), a recent study (Buck et al. 2011) has explored the use of biological controls, which could potentially aid in disease mitigation. The authors show in this paper that the zooplankton *Daphnia magna* consumes the infective stage of *Bd*, aquatic zoospores, 3–5 µm in diameter. According to previous studies, *Bd* infection leads to host mortality when a threshold density of sporangia is reached. By consuming infective *Bd* zoospores, *D. magna* may limit the numbers to below the mortality threshold. The authors suggest that increasing zooplankton densities where they are deficient could help at-risk anuran populations persist despite the presence of *Bd*.

Environmental DNA Used to Detect Presence of Stream Amphibians

Methods for detecting the presence of aquatic organisms by assaying water samples for their DNA (environmental, or "eDNA" methods) have become useful tools for wildlife managers, such as in monitoring the spread of invasive species. Most applications of these methods have been in large bodies of standing or slowly moving water. The authors of this paper employed these methods to determine their effectiveness in detecting a pair of high-gradient, low-order stream amphibians: Idaho Giant Salamanders (Dicamptodontidae: *Dicamptodon aterrimus*) and Rocky Mountain Tailed Frogs (Ascaphidae: *Ascaphus montanus*). Water samples were taken in the spring and fall from streams known to be inhabited by these species. These streams were also evaluated for these species' larval densities. This water was passed through a filter, which was then subjected to several well-established molecular genetic methods for extracting and amplifying DNA. The authors were successful in detecting both species in the streams despite variability of success among the methods. Fall samples had a higher frequency of detection than spring samples, which the authors attribute to the reduced metabolic activity exhibited by these species early in the year. Indeed, detection was largely influenced by species and season, with no apparent correlation with density. The authors emphasize the utility of these methods in lotic systems and the promise they hold for assessing the presence of rare or otherwise hard to detect aquatic vertebrates.

Female Lacertid Lizards Can Use Scent to Determine Male Body Size

Although female mate choice is common in vertebrates, conclusive evidence demonstrating female choice in lizards is rare, especially in territorial species. Territoriality complicates female choice because females have access to relatively few males (depending on the relative sizes of male and female home ranges) or incur significant fitness costs sampling males far from home. Despite this, recent studies have shown that females of some territorial lizard species in the family Lacertidae can use scent marks to assess subtle aspects of male fitness, such as body condition, social dominance and parasite load. Additionally, males of the lacertid *Podarcis hispanica*, have been shown to use scent to assess important traits, such as body size, of rival males. However, the importance of similar scent marks in female mate choice in this species is unknown. In this study, the authors have examined whether female *P. hispanica* can use scent marks to determine male traits and if they can, how they use this information. Female lizards caught in Valencia, Spain, were simultaneously exposed to three choice areas marked with either the scent of a small male, the scent of a large male or a control (no scent). Results indicated that females preferentially associated with scent marked choice areas, but did not distinguish between large and small males. Interestingly, when exposed to simulated dusk conditions, females preferentially sheltered in refuges scented marked by small males. The authors suggest that these results are evidence that females of this species, like males, can determine body size from scent markings. The observation that females preferentially associate with males in simulated dusk may be a strategy to avoid the costs of harassment or forced copula by large males.

Daryl R. Karns
July 23, 1949—June 7, 2011

Daryl Ralph Karns died unexpectedly at age 61 on June 7, 2011, near his home in Madison, Indiana. He left a legacy of global scientific research in the field of amphibians and reptiles, and a teaching career that spanned 27 years at Hanover College in Hanover, Indiana. Karns was born the son of Ralph R. and Lillian M. Heinze Karns on July 23, 1949. He is survived by his wife, Dr. Pamela A. Middleton, his brother, Rodney Karns, his sister, Jarmila Fuller, and their families. He grew up in Homewood, Illinois, on the far southeast side of Chicago and attended the Homewood-Flossmoor Community High School.

PHOTO BY SANDRA GUTHRIE

FIG. 1. Professor Daryl R. Karns, 23 July 1949 – 7 June 2011. This photograph was taken in March of 2011 adjacent to the trail head of the nature trail system now named *The Daryl R. Karns Natural History Trails* on the campus of Hanover College, Hanover, Indiana.

While a student at Homewood-Flossmoor High School, Daryl considered a career in theater and participated in the debate team. He loved to recall that at more than one debate competition he found himself paired up with John Belushi, from New Trier Township High School. However Daryl's career path was strongly influenced by other experiences. Foremost were several school field trips to the Field Museum of Natural History in Chicago where Daryl became a young expert on dinosaurs and other vertebrates. These were capped off with a personal "field trip" arranged by a close friend of his mother's to the home of Karl P. Schmidt, Chief Curator of Zoology at the Field Museum, who was also a resident of Homewood, Illinois. Thirty years later, sitting in what had been Schmidt's office at Field Museum, Daryl would recall the details of the artifacts in K. P. Schmidt's home "museum" and how it stimulated his interest in natural history.

For his undergraduate work Karns attended the University of Wisconsin-Madison from which he received his bachelor's degree in zoology in 1972. He went on to the University of Kansas where he served as a curatorial assistant in the paleontology collection at the Dyche Museum of Natural History, and earned a master's degree in systematics and ecology in 1974. While at the University of Kansas, he planned and designed a series of field identification guides to the vertebrates of Kansas utilizing an illustrated flow chart (Karns et al. 1974).

Next Karns joined the U.S. Peace Corps which led to his assignment in Senegal, West Africa, as a research scientist in the Smithsonian Institution-Peace Corps Environmental Program (SI-PCEP) from 1974 to 1976. SI-PCEP was an international initiative to develop biodiversity and conservation biology projects. While serving in Senegal, Karns collaborated with Mamadou Cissé of the Département de Zoologie des Vertébrés terrestres at the Institut Fondamental d'Afrique Noire (IFAN) and the University of Dakar. They conducted surveys and later published papers on the systematics and ecology of Senegalese lizards (Cissé and Karns 1977, 1978; Karns and Cissé 1975). Two of the three Cissé and Karns papers were published in French in the *Bulletin de l'Institut Fondamental d'Afrique Noire*.

Following his work in Senegal, Karns initiated his Ph.D. work at the University of Minnesota (Minneapolis). There he worked as a curatorial assistant and research assistant at the James Ford Bell Museum of Natural History, while conducting his doctoral research in the Department of Ecology and Behavioral Biology at the University under the direction of Professor Philip Regal. His research, which involved extensive field work in the peat bogs of northern Minnesota, focused on the effects of acidic bog habitats on amphibian reproduction (Karns 1984). Whenever Daryl talked about the temperature extremes and insect concentrations that he encountered during his year-round visits to the bogs, it gradually became clear that he really loved the challenges that came with working in difficult habitats.

Karns received his Ph.D. in 1984, and later published much of his thesis research in the *Journal of Herpetology* (Karns 1992a), and in a chapter on amphibians and reptiles in *The Patterned Peatlands of Minnesota* (Karns 1992b). In 1986, he published an 88-page guide to field study techniques entitled *Field Herpetology: Methods for the Study of Amphibians and Reptiles in Minnesota,* based on his field work experience in Minnesota and his studies at the University of Kansas (Karns 1986a). It was funded by the Minnesota Department of Natural Resources (MDNR) and the James Ford Bell Museum of Natural History. Karns geared the guide to amateur naturalists, citizen-scientists, agency personnel, and teachers in Minnesota. However the techniques are applicable beyond the Great Lakes region and include extensive coverage of drift fence and funnel trapping, breeding call surveys, and museum specimen preparation. This guide is still useful for undergraduate and graduate field biology courses. It is available as a pdf on the MDNR website. (http://files.dnr.state.mn.us/eco/nongame/projects/consgrant_reports/1986/1986_karns.pdf).

Karns joined Hanover College as an assistant professor in 1984. He was promoted to associate professor in 1990, and to

HAROLD K. VORIS*
e-mail: hvoris@fieldmuseum.org
ALAN RESETAR*
e-mail: aresetar@fieldmuseum.org
JOHN MURPHY*
e-mail: fordonia1@comcast.net
**Department of Zoology, Field Museum of Natural History, 1400 S. Lake Shore Drive, Chicago, Illinois 60605, USA*

full professor in 1997. He was also appointed Interim Director of the Rivers Institute at Hanover College for 2004–2005, and subsequently to the position of Director of Science Programs at the Rivers Institute.

While he was at Hanover, Karns met fellow college professor Pamela A. Middleton, whom he married in 1996. Pam received her M.D. that same year, having returned to medical school several years before. While Pam was participating in a medical program in Kenya as part of her training, Daryl returned to Africa to join her for travel, and it was there that he proposed.

From the time he arrived at Hanover Daryl was an enthusiastic and vibrant teacher who brought his passion for research into the courses he taught: introductory biology, biodiversity, herpetology, tropical biology, ecology, evolution, conservation biology and comparative anatomy of vertebrates. He also directed numerous student independent study projects, and his enthusiasm for working with students was characterized by energy, sensitivity, and genuine concern for their welfare and career paths.

Among Daryl's first field projects at Hanover College in 1985 and 1986, was an ecological study of the herpetofauna of the Jefferson Proving Ground (JPG), Clifty Falls State Park and natural areas on the Hanover campus, all located in Jefferson County (Karns 1986b, 1994). The JPG is a former weapons testing facility (closed in 1995) that is now partly within the 20,200 hectare Big Oaks National Wildlife Refuge. He was a key researcher at Big Oaks National Wildlife Refuge where he was a member of the Big Oaks Conservation Society and founder of the Heritage Conservancy, a trust to protect area lands. On the Saturday before his death Daryl had been out at Big Oaks, serving as an instructor at one of their public events and working with students on independent projects. Joe Robb, refuge manager at Big Oaks, had worked closely with Karns since 1998, and recalled that "Daryl had a level of curiosity and enthusiasm that was infectious."

In May 2007, Karns instituted the first BioBlitz at Hanover, a 24-hour intense species inventory of the campus. Daryl was a BioBlitz enthusiast and was one of the major organizers of BioBlitzes held by the Indiana Academy of Science. He, his students, and Indiana herpetological colleagues could always be counted on to participate. Karns also served as adviser to the campus Nature/Outdoors Club and directed numerous other off-campus environmental projects statewide.

The Indiana Department of Natural Resources established committees to review annually the conservation status of nongame animals. Karns joined the Nongame Amphibian and Reptile Technical Advisory Committee in 1985, and was chair from 1991 to 1999. Early meetings were held in the living room of Dr. Sherman Minton Jr., Indiana's premier herpetologist. Several hours of discussing Indiana herpetological matters were followed by lunch with persimmon pie for dessert, prepared by Madge Minton. In 1996, as chair of the Indiana Academy of Science Organizing Committee, Karns, and his wife Dr. Middleton, were instrumental in planning and conducting a celebration of the life and career of Dr. Minton on the occasion of the publication of the second edition of his book, *Amphibians and Reptiles of Indiana* (Minton 2001).

For the past 21 years, Daryl Karns was a primary investigator in field research at the Field Museum of Natural History that was so much a part of his early life. This began in the summer of 1989, when Daryl first met Harold K. Voris, Curator of Amphibians and Reptiles, at the American Society of Ichthyologists and Herpetologists meetings in San Francisco and they discovered their common connections with both Hanover College and the Field Museum. At that time Robert F. Inger and Voris were conducting a number of systematic herpetological surveys in Southeast Asia. They had initiated surveys in 1986 at Danum Valley in the Malaysian state of Sabah on the island of Borneo, and Harold's invitation to Daryl to join him for the work in Borneo proved too much for Daryl to resist. Harold vividly recalls Daryl's great excitement—especially since his primary research interest was in evolutionary ecology—on taking his first trip to Borneo where Alfred Russel Wallace had made evolutionary history through his collections and reports on the vast tropical diversity of Southeast Asia.

Daryl's formal affiliation with the Field Museum began in 1990 as a Research Associate. It was the beginning of an extremely productive period in his life in which he worked with Harold Voris, researching amphibians and reptiles of Southeast Asia, especially the aquatic snakes. But Daryl's affiliation with the Field Museum was more than a formality—he became a valued and welcomed member of the Field Museum community. He conducted tours for Field Museum, participated in Members' Nights, attended seminars, brought Hanover students to work there during the summers, and in general he became a Field Museum "regular" whose company and keen mind were enjoyed by all. At one point Daryl reflected on this experience, saying, "I was raised in the south suburbs of Chicago and visited the Field Museum many times as a child. Today, it is still a thrill for me every time I walk into the central hall of the Field Museum, one of the great museums of the world, and disappear behind those mysterious doors labeled 'Research Staff Only.' My Research Associate position over the last 14 years has allowed me to do things and go places that belong in the domain of National Geographic specials."

By 1992, Daryl began to work with Harold on the aquatic snakes of Southeast Asia with an emphasis on homalopsid snakes (Karns and Voris 1996). They began with field studies on *Enhydris plumbea* in an abandoned rice paddy in Sabah, Borneo. This wetland habitat was located with the help of Rob Stuebing, a faculty member of the University of Malaysia, Sabah campus.

FIG. 3. Daryl Karns (on right) with John C. Murphy in Voris' research lab in the Division of Amphibians and Reptiles at the Field Museum of Natural History, March 2004.

Daryl and Harold benefited greatly from the generous logistical support and hospitality of Rob and his family, as well as that of the staff and administration at the Sabah State Museum. In fact, it was in Rob's lab that Daryl was bitten on the thumb by a large female *E. plumbea* while applying a PIT tag. After calmly removing the snake from his thumb he continued to work while remarking on how it stung. Later at a local coffee shop Daryl held his thumb in an iced coffee, hoping that it would reduce the swelling but it just drew stares. *Enhydris plumbea* is mildly venomous and much later the photograph of the bite on Daryl's thumb made it into print (Norris and Minton 2001) with an unintentional twist that became the basis for later joking—in the figure caption the snake identification was scrambled and *Enhydris plumbea* became *"Enhydrina plumbea"—Enhydrina* being a genus of extremely deadly true sea snake! After that Voris liked to introduce Karns to fellow herpetologists as the guy who suffered an *Enhydrina* bite and lived to tell about it!

Under the sponsorship of the Prince of Songkhla University in Hat Yai (Thailand) and Dr. Vachira Lheknim, a four-year project on the ecology of *Enhydris enhydris* on the edge of Lake Songkhla was initiated in 1995 by Karns and Voris. During this project Jack and Raynoo Cox generously provided hospitality in Bangkok that included many wonderful Thai meals at their home and in the numerous great local restaurants. This project was the first in which John Murphy (also a Research Associate at Field Museum), Harold, and Daryl worked together in the field and from this point on they worked as a research team. Daryl's enthusiasm in the field was very contagious. He was always interested in following the trail for another kilometer or looking over the next hill despite temperature extremes or rain. Typically, while exploring Angkor Wat in Cambodia one steamy sunny day, Daryl decided that he should not pass up climbing to the top of a Khmer pyramid despite the fact that the temperature was well above 40°C!

During Daryl's 2001–2002 sabbatical, the team focused on the ecology of mangrove-dwelling snakes at two locations on the island nation of Singapore. This work was sponsored and generously hosted by the faculty and students of the National University of Singapore (NUS) and the Raffles Museum of Zoology. It was here, with the industrious efforts of Siva (N. Sivasothi) at NUS that the "Snake Hunters" group was formed. This was a volunteer group of about 30 students and local naturalists who worked with the Field Museum team to conduct nightly snake surveys in local mangrove swamps. Bruce Jayne (University of Cincinnati and Field Museum Research Associate) also joined this effort, conducting feeding studies on two species of crab-eating homalopsids. Daryl's focus was on radio-telemetry of both the Bockadam Snake (*Cerberus rynchops*) and the Crab-eating Snake (*Fordonia leucobalia*). In this work he excelled. His trademarks—keen interest, patience, and careful data management—allowed him to succeed in tracking snakes in mangrove swamps, certainly among the most challenging habitats to work in on our planet (Karns et al. 2002).

Daryl's final field work in Southeast Asia began in 2004 with a focus on several species of snakes in Indochina, the center of distribution of the family Homalopsidae. This research was sponsored by Chulalongkorn University in Bangkok and the faculty and students of the Thai Turtle Lab led by Dr. Kumthorn Thirakhupt as well as Tanya Chanard and many others at the National Science Museum of Thailand. Our aim was to learn as much as possible about the natural history, ecology, distribution, dispersal abilities, and population relationships of the species in Thailand's wetlands. This field work extended through 2007 and left us with an inventory of results on three fascinating species: *Enhydris enhydris*, *E. plumbea*, and *E. subtaeniata*.

Karns' work on homalopsid snakes also became a vehicle for involving a number of Hanover College students in research at the Field Museum, in Singapore and Thailand, as well as at Hanover, yielding a long list of "homalopsid alumni"—biology majors who worked on homalopsid snake research at some point during their years at Hanover, usually as part of their respective independent studies. Financial support for these projects came from the Hanover College Richter Fund, the Rivers Institute Grant Committee, the Field Museum, the MacArthur Foundation, and the National Geographic Society. Students Jeff Goodwin, Ashley O'Bannon, Luke Starnes, Emma Thompson, Tom Goodwin, Emily Abernathy, Stacey Sellins, Jerry Suddeth, Bobak Kechavarsi, and Megan Rinehart co-authored published papers that resulted from their work. The majority of these students have continued their education in professional and graduate schools and pursued careers in science. Several decided to change career plans and go into research because of their Field Museum experience.

A prolific writer and presenter, Karns published nearly 40 peer-reviewed journal articles and technical reports. He authored or was involved in 18 popular articles, reviews, and videos, contributed 31 conference papers, and gave 43 seminars and public presentations. In addition, he secured a number of grants, awards, and fellowships for the College. As in the field work, during the data analysis and writing phase of our collaborations, Daryl's enthusiasm for discovery coupled with his careful analyses and love for scientific writing made working with him a joy. His skills as a proofreader extraordinaire and honest critic made him indispensable to our program. Tragically, Daryl's untimely death occurred before he could learn that a homalopsid snake species new to science was being described in his honor by John Murphy (Murphy 2011). Naming this new species after Daryl was a highly deserved tribute to his many contributions to our knowledge of homalopsid snakes, and he would have considered it one of his highest honors.

Karns will be remembered at Hanover for being an outstanding teacher, dedicated faculty member and colleague, and for his wide-ranging contributions to the Rivers Institute. To recognize the many significant contributions he made to his field, Karns received the first annual Hanover College Faculty Award for Excellence in Scholarly and Creative Activity at this year's Honors

Convocation, held April 7, 2011. The College has now renamed this award "The Daryl R. Karns Award for Faculty Scholarship and Creative Activity" in recognition of his many contributions and his exceptional academic standards, and as a memorial to its first recipient. In an additional tribute, at the memorial service held for Daryl on the campus of Hanover College, June 12, 2011, the President of the College officially named the nature trail system at the College, *The Daryl R. Karns Natural History Trails*.

Daryl had many wonderful characteristics that stood out in all the arenas of his life: he was a hard worker, very reliable, always respectful of others, and had great personal and intellectual integrity. His positive outlook, enthusiasm, and great sense of humor made us all want to have his companionship throughout our lives. He will be greatly missed by his many students, colleagues and friends at Hanover College, at Field Museum and in the field of herpetology at large.

Acknowledgments.—We thank Helen Voris for her assistance in the preparation of the manuscript and careful editing. Dr. Susan Weller, Director, James Ford Bell Museum of Natural History, checked the Bell Museum archives for photos of Daryl and gave us permission to use a photograph of him from his *Field Herpetology* publication. Mary Markey, Reference Archivist, Smithsonian Institution Archives, investigated the records of Daryl's service in the Smithsonian Institution-Peace Corps Environmental Program. We also thank Dr. Pamela Middleton, Celeste Sutter, and the staff and faculty at Hanover College for their assistance in locating photographs and background information.

A Brief History of Crocodilian Science

The recent history and development of crocodilian science, and the people who made advances through pioneering studies on crocodilians spans more than 300 years. However, crocodilians were well known to ancient people thousands of years ago. Crocodilians were considered gods for their seemingly mystical powers, procreative ability, and longevity. Ptolemy X and Alexander I dedicated a temple to the crocodile god *Sebek* or *Souchos* about 95 BC. Crocodiles were accepted as the national emblem of Egypt and the Ptolemys, and appeared on imperial Roman coins. Lest we consider ourselves innovative in our care of zoo crocodilian collections, we should remember that the early Romans brought men from distant regions that were reported to have special skills to care for captive crocodiles (Grant 1992).

Although crocodilians and their ancestors have been around for about 200 million years, crocodilian science is relatively new. In this paper we attempt to put into perspective the history of crocodilian science and the people who were, and are today, part of this ongoing story. It is a starting point to be continued. The inclusion or omission of anyone in this paper should not be construed to discredit or endorse anyone or their work. It is not possible to include each and every scientist who worked in some aspect of crocodilian sciences. The majority may have conducted crocodilian research for specific projects and then moved on to other interests. Others have made crocodilian science their life's work. Some folks were lucky enough to be in the right place at the right time, with the right interests. Some still are making crocodilian history.

Periods in crocodilian science.—The history of crocodilian science falls into periods of special interest, each with its own focus and direction (Table 1). Scientific knowledge of crocodilians found its infancy during the golden period of global exploration and colonization. It was a time when the great nations of the world were establishing colonies, business interests, missions, and government offices in far-away regions where the fauna and flora were often new to science and a topic of curiosity. Government offices were often staffed by people with considerable education and wide interests. Many of today's great museum collections reflect the hunting activities and hobbies of district officers, government hunters, and "amateur" naturalists of the time, who collected and catalogued the rocks, insects, animals, and plants as a digression from the hardships and boredom of performing their official duties far from home.

Western science only became aware of the presence of a Chinese Alligator (*Alligator sinensis*) when it was reported by a Shanghai Customs Officer, A. A. Fauvel, in 1879 (Fauvel 1879), although it was known to Chinese scholars for 3,000 years.

It is also during this period that many of the world's greatest museums were built. They became homes to the new breed of naturalist-scientists, and where heretofore unknown and unnamed specimens, including crocodilians, often found their way. They now make up the voucher collections that form the

Table 1. Historic events in crocodilian science.

Year	Event
1758	A system of classification described (Linnaeus 1758)
1768	Class Reptilia (Laurenti 1768)
1933	Mixed species of crocodilians exhibited, Bronx Zoo, NY (DeSola 1933; Ditmars 1913)
1935	First observations of wild American Alligators (McIlhenny 1935)
1963	Sexing technique developed for all crocodilian species (Brazaitis 1968)
1964	First museum quality record keeping system for zoos (Dowling and Gilboa 1968)
1966	Endangered Species Act, amended 1969, 1981, 1988
1970	Nesting ecology of alligators — field study (Joanen 1970)
1970	First crocodilian genetics study (Cohen and Gans 1970)
1971	IUCN Crocodile Specialist Group founded
1971	Species identification of crocodilian hides and products (King and Brazaitis 1971)
1973	Comprehensive identification account of living crocodilians (Brazaitis 1973a)
1973	Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES)
1977	First crocodilian behavior studies (Garrick and Lang 1977)
1980	First SSP/studbook initiated to coordinate breeding efforts for Chinese Alligator (Behler)
1980	Maternal behavior and vocalization, young and mother (Watanabe 1980)
1982	Temperature dependent sex determined (Ferguson and Joanen 1982)
1983	Biochemical and immunological systematics of Crocodylia (Densmore 1983)
1986	AZA Crocodilian Advisory Group founded
1986	St Augustine Alligator Farm joins AZA
1989	Social displays of American Alligators (Vliet 1989)
1994	Genetic fingerprint profiles described (Aggarwal et al. 1994)
2003	Phylogenetic approaches toward crocodilian history (Brochu 2003)
2006	*Mecistops* resurrected (McAliley et al. 2006)
2007	*Tomistoma* into Family Gavialidae (Willis et al. 2007)
2008	Molecular support for intergeneric crocodylian relationships (Gatesy and Amato 2008)
2009	Barcoding of crocodilian meat for species identification (Eaton et al. 2009)

Table 2. Natural history museums holding significant crocodilian collections.

Museum	Established
The Muséum national d'Histoire naturelle, Paris, France	1793
The National Museum of Brazil, Rio de Janeiro, Brazil	1818
Louis Agassiz Museum of Comparative Zoology, Harvard University, Cambridge, MA, USA	1859
The American Museum of Natural History, NY, USA	1869
Natural History Museum (British Museum), London, UK	1880
Florida Museum of Natural History of the University of Florida, Gainesville, FL , USA	1891
Field Museum of Natural History, Chicago, Ill, USA	1893
National Museum of Natural History, Smithsonian Institution, Wash. D.C., USA	1910
Senckenberg Natural History Museum, Frankfurt, Germany	1914
Yale Peabody Museum of Natural History, New Haven, CT, USA	1866

basis for the comparative studies that are so important to our understanding of animal relationships. Large crocodiles were often killed because of the danger they posed to people. Thus, the largest crocodile skulls found in collections today are usually animals killed out of necessity or sport, often dating back to the mid-to-late 1800s and early 1900s.

Although regional museums may have extensive collections of native species, or specialize in certain taxa, those museums that enjoyed national prestige or university support amassed collections representing species from around the world. Museums also made expeditions to remote or little known regions to fill their collections. For example, the expeditions of the Chicago Field Museum of Natural History to the Philippines in the 1930s produced extensive collections that included crocodilians, and yielded the first description of *Crocodylus mindorensis*, the Philippine Crocodile (Schmidt 1935). With the advent of molecular studies of crocodilians (Aggarwal et al.1993; Amato 1991, 1994; Amato et al. 1998; Cohen and Clark 1967; Cohen and Gans 1970; Densmore 1983; Densmore and Owen 1989; and many others), it became necessary for museum collections to change their specimen preparation methods and increase their storage. Tissue collections often grew out of research by individual scientists and the most extensive tissue collections are maintained in university museum collections or other research facilities. Several museums house collections of crocodilian specimens that are significant either in terms of specimen count, taxonomic importance, or historical value (Table 2).

Taxonomy.—Endemic people certainly were aware of the ferocious beasts that lived in nearby rivers and swamps, possibly accounting for a sudden disappearance of friends or family last seen bathing in the river. But crocodilians as a living group attracted scholarly interest after the Swedish botanist, zoologist, and physician Carolus Linnaeus published *Systema Naturae* in 1758 and 1766 (*Systema naturae per regna tria naturae, secundum classes, ordines, genera, species, cum characteribus, differentiis, synonymis, locis*. Translated: "System of nature through the three kingdoms of nature, according to classes, orders, genera and species, with characters, differences, synonyms, places").

Linnaeus provided an organized system of classification that still stands, based on a division of Kingdoms: *Regnum Animale*, *Regnum Vegetabile* and *Regnum Lapideum*—animals, plants, and minerals. The tenth edition of this book, published in 1775, is considered the starting point of modern zoological nomenclature. The works of Laurenti (1768) and Linnaeus (1758, 1766) heralded a truly scientific period of interest in classifying all living creatures, including crocodilians.

Fig. 1. Gerard Krefft (1830–1881) (http://wikipedia.org/wiki/File:Krefft_Gerard_1830-1881.png).

Nearly all of the crocodilian species we know today (Table 3) were originally described between 1758 and 1828 (Table 4), with the exception of two species: the New Guinea Crocodile (*Crocodylus novaeguineae*) in 1928, and the Philippine Crocodile (*C. mindorensis*) in 1935 (Table 1). An overview of the original descriptions of reptiles is given by Uetz (2010).

The International Commission on Zoological Nomenclature was founded in 1895 and publishes the *International Code of Zoological Nomenclature* (ICZN) (1961). Probably one of the most interesting application of ICZN rules occurred in the naming of the Australian Johnston's Crocodile.

Johann L. G. Krefft, Director of the Australian Museum (Fig. 1), had sent a plaster cast (Fig. 2) of a crocodile discovered by a Mr. Johnston of Cardwell, Rockingham Bay, Queensland, Australia, to Dr. John Edward Gray (Fig. 3), Keeper of Zoology at the British

TABLE 3. Crocodilian species and their global distribution, derived from Brazaitis (1973), King and Burke (1989), Sill (1968), Thorbjarnarson (1992, 1996).

Species	Common name	Modern distribution
Family: Alligatoridae		
Genus: *Alligator*		
A. mississippiensis	American Alligator	North America: SE USA
A. sinensis	Chinese Alligator	Asia: middle Yangtse River - Wuhu, Anhui Province
Genus: *Caiman*		
C. crocodilus	Caiman	Central and South America
C. c. crocodilus	Common Caiman	S. America: Amazon River drainage basin
*C. c. apaporiensis**	Rio Apaporis Caiman	S. America: east of the Andes; middle Rio Apaporis
C. c. fuscus	Rio Magdalena Caiman	S. America: northern Andes: Rio Magdalena, Atlantic drainage; northwestern Venezuela
C. c. chiapasius	Central American Caiman	Mexico, C. America and S. America: west of the Andes
C. latirostris	Broad-snouted Caiman	South America
C. l. latirostris	Broad-snouted Caiman	S. America: W and S Atlantic drainages of Brazil, Paraguay, Uruguay, northern Argentina
*C. l. chacoensis**	Argentine Broad-snouted Caiman	South America: northern Argentina; Paraguay, Parana river drainages
C. yacare	Yacare Caiman	South-central S. America: Paraguay, Parana, Guapore river drainages, not Amazon
Genus: *Melanosuchus*		
M. niger	Black Caiman	S. America: Amazon River basin and drainages
Genus: *Paleosuchus*		
P. palpebrosus	Dwarf Caiman	S. America: tropical S. America
P. trigonatus	Smooth-fronted Caiman	S. America: Amazon (forest) basin
Family: Crocodylidae		
Genus: *Crocodylus*		
C. acutus	American Crocodile	N. and S. America: S. US; neotropical: Mexico, Central America; west coast S. America, Peru to Venezuela; Caribbean Islands
C. intermedius	Orinoco Crocodile	South America: Orinoco River and drainages
C. johnsoni	Johnston's Crocodile	Australia: northern territories
C. mindorensis	Philippine Crocodile	Western Pacific: Philippine Islands
C. moreletii	Morelet's Crocodile	Central America: Atlantic drainages; Mexico, Belize, Guatemala
C. niloticus	Nile Crocodile	Africa: Sub-Sahara, historically to Israel and Jordan; Madagascar
C. novaeguineae	New Guinea Crocodile	Western Pacific: Indonesia and Papua New Guinea
C. palustris	Mugger or Marsh Crocodile	South Asia, Indian sub-continent
C. p. palustris	Indian Marsh Crocodile	South Asia, Indian sub-continent: lowland India, Pakistan
*C. p. kimbula**	Ceylon Marsh Crocodile	South Asia: Sri Lanka
C. porosus	Saltwater Crocodile	N. Australia, SE Asia, India, Western Pacific, Palau, Solomon Islands, Vanuatu
C. rhombifer	Cuban Crocodile	Caribbean: Zapata Swamp, Isle of Pines
C. siamensis	Siamese Crocodile	SE Asia and Malaysia (historical); recent Laos, Cambodia
Genus: *Mecistops*		
M. cataphractus	African Slender-snouted Crocodile	Central West Africa: mostly tropical forest
Genus: *Osteolaemus*		
O. tetraspis	Dwarf Crocodile	Central West Africa
O. t. tetraspis	West African Dwarf Crocodile	Central West Africa: mostly tropical forest
O. t. osborni	Congo Dwarf Crocodile	Central West Africa: Congo Basin
Family: Gavialidae		
Genus: *Gavialis*		
G. gangeticus	Indian Gharial	India, Indian sub-continent: rivers of northern India and eastern Pakistan
Genus: *Tomistoma*		
T. schlegelii	Malayan False-gharial	SE Asia: lowlands of Thailand, Malaysia, Indonesia

*Subspecies not recognized by all authorities.

Museum, London. Krefft had earlier sent Gray a photograph in 1871, and had described the crocodile in a subsequent publication (Krefft 1873), where he called the taxon *Crocodylus johnsoni*, misspelling the name of the discoverer. Gray (1874) called attention to the error—but too late. The error stands to this day, in accordance with the rules of the International Commission on Zoological Nomenclature: once misspelled always misspelled with few exceptions. Taxonomists have revisited crocodilian systematics many times over the years (Boulenger 1889; Brazaitis 1971, 1973a, 1973b; King and Burke 1989; Mertens 1943; Mook 1921; Wermuth and Mertens 1977; Werner 1933). Determining the relationships among species draws more heavily on molecular data than physical appearance in modern studies. However, given the rich fossil diversity of the group, studies involving both molecular data and paleontology were inevitable (Brochu 2001a, 2001b, 2003; Brochu and Densmore 2001). Conservation genetics laboratories, such as those at the American Museum of Natural History's Center for Conservation Genetics (New York), Texas Tech University's Department of Biological Sciences (Lubbock, Texas), and the Yale Institute of Biological Sciences, Molecular Systematics and Conservation Genetics Laboratory (New Haven, Connecticut), have emerged as important centers for crocodilian genetics research.

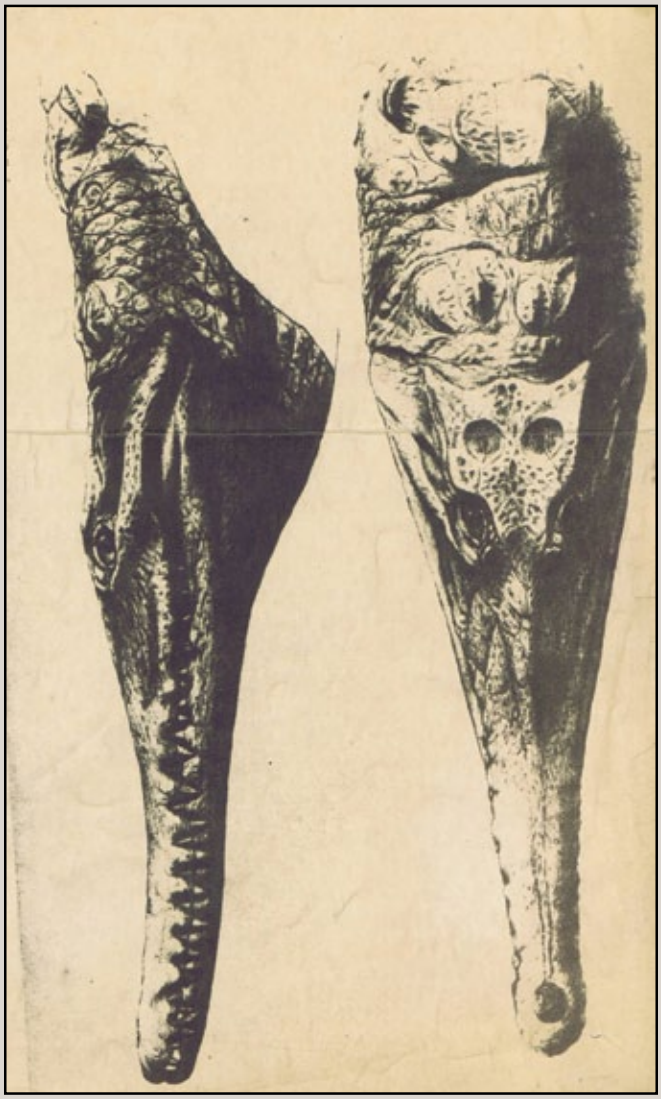

FIG. 2. Plaster cast of head of originally described as Johnston's Crocodile, *Crocodylus johnsoni*. (Adapted from Krefft 1873).

Disparities in morphology-based phylogenies and those based on molecular studies, as well as the impact of technical advances in phylogenetic analysis soon became apparent (Brochu 1997, 2001b; Gatesy and Amato 2008; Poe 1996; Willis 2009). Crocodilian phylogeny continues to be rearranged (Gatesy and Amato 2008), most recently with the transfer of *Tomistoma* from the Crocodylidae to Gavialidae (Willis et al. 2007), and the reassignment of *Crocodylus cataphractus* to the genus *Mecistops* (McAlily et al. 2006).

Crocodilian morphology and physiology.—The structure and morphology of crocodilians continues to interest and astound scientists and lead to discoveries as technologies improve. Few modern crocodilian morphologists can rival the early anatomical works of Albert M. Reese. Between 1901 and 1948, Reese published more than 30 papers ranging from bibliographies of crocodilian literature to all aspects of crocodilian anatomy and biology (Reese 1915). Angus d'Albini Bellairs, an evolutionary biologist, published extensively on crocodilian structure and evolution (Bellairs 1960).

Roland A. Coulson, Louisiana State University, published more than 50 papers on alligator metabolism between 1950 and 1983, pioneering much of what we know of how crocodilians function and use energy (Coulson and Hernandez 1964). His colleague, Thomas Hernandez, published at least 30 papers in a similar period (Hernandez and Coulson 1952). The Louisiana State University, Baton Rouge, continues to be a major resource for crocodilian management, nutrition, and veterinary science.

Perhaps some of the most important contributions to our knowledge of crocodilian eggs and embryonic development came from Mark W.J. Ferguson, a young oral surgeon at Queen's University in Belfast, Northern Ireland, with an interest in human cranial-facial reconstruction. The palatal development of

FIG. 3. John Edward Gray (1800–1875) (http://en.wikipedia.org/wiki/John Edward Gray).

alligators during developmental stages had direct application to his human work, and provided crocodilian science with an understanding of the stages of incubating alligator eggs and embryonic development (Ferguson 1981). Ferguson and Ted Joanen at Rockefeller Wildlife Refuge, in Louisiana, were the first to describe incubation temperature dependent sex determination in a crocodilian (Ferguson and Joanen 1982).

Saving crocodilians: a new era for crocodilian science.—The late nineteenth through the twentieth century were not kind to crocodilians. By 1971, burgeoning human populations encroaching on crocodilian habitat and abusive hunting for the exotic leather and pet trade threatened all of the commercially valuable species with extinction. Hunting meat for human consumption was a serious threat to crocodilians and continues today (Eaton et al. 2009). Demand from the exotic leather industry in particular had almost destroyed the very resource upon which the industry depended. Something had to be done.

In March 1971, the first meeting of crocodilian specialists was held at the Bronx Zoo Reptile House in New York. It was a precursor to the present IUCN Crocodile Specialist Group (CSG) and included zoologists, recognized crocodilian experts, conservation interests, and representatives of the crocodilian leather industry from around the world (Fig. 4).

Under the leadership of Harry Messel, Professor of Physics and Head of the School of Physics at the University of Sydney, and F. Wayne King (then Curator of Reptiles, Bronx Zoo), University of Florida, the CSG was the first and perhaps most successful of the Specialist Groups. It adopted a strategy for the conservation of crocodilians that was based on the sustainable utilization of a valuable wild resource. Crocodilians as a whole did not enjoy a favorable public image and were generally considered dangerous. However, their skins were well known to be of significant commercial value.

The CSG actively partnered with the commercial crocodilian skin industry to provide assistance in surveying and documenting the extent and health of wild crocodilian populations, developing a tailored strategy for utilization, and encouraged national regulation that might be favorable to both commercial trade and crocodilian conservation. Crocodilian conservation was inextricably tied to the market value of skins. Generally speaking, commercially valuable crocodilian species have particularly benefited from the collaborative strategy. Captive propagation has improved the numbers of animals of endangered species held in captivity many fold and made many thousands of skins available for commercial trade that might otherwise have come from wild populations.

However, wild populations of a number of species continue to decline for lack of conservation funding, continued loss or the degradation of critical habitat, and abusive hunting for bush meat and holistic medicines. These include critically endangered species such as the Chinese Alligator (*Alligator sinensis*), Philippine Crocodile (*Crocodylus mindorensis*), Orinoco Crocodile (*C. intermedius*), Indian Gharial (*Gavialis gangeticus*) and Malayan False Gharial (*Tomistoma schlegelii*), and perhaps the Cuban Crocodile (*C. rhombifer*), African Slender-snouted Crocodile (*Mecistops cataphractus*), and Mugger or Marsh Crocodile (*C. palustris*) (Table 3). Large-scale captive management of closely related species for enhancing skin production has also led to the purposeful hybridization of large numbers of otherwise rare species, such as Cuban Crocodiles and American Crocodiles *(Crocodylus acutus*); Siamese Crocodiles (*C. siamensis*) and Saltwater Crocodiles (*C. porosus*); and multiple species of caiman (*Caiman crocodilus*), possibly threatening the genetic integrity of some already endangered species (Brazaitis and Abene 2008).

Fig. 4. Top row from left to right: Tony Pooley, Nile Crocodiles, Natal Parks Board, South Africa; Max Downs, New Guinea Crocodiles, Papua New Guinea; Peter Brazaitis, Reptile Keeper, Bronx Zoo, NY, USA; Prof. Angus A. d'A. Bellairs, evolutionary biologist and anatomist, UK; Dr. Robert Bustard, Indian and Australia crocodilians; Dr. Hugh Cott, African ecology of the Nile crocodile, UK; Dr. F. Wayne King, conservationist, Curator of Reptiles, Bronx Zoo, NY; Prof. Federico Medem, South American crocodilian biologist, Instituto Roberto Franco, Colombia. Front Row: Moira A. G. Warland, IUCN; Mrs. Clare Hagan, CEO, Hagan and Co., New York; Utai Yangprapakorn, Samut Prakarn Crocodile Farm and Zoo, Thailand; Dr. Robert (Bob) Chabreck, Louisiana Department of Fur, Fish and Game, Louisiana, USA; Charoon Yangprapakorn, Thailand; James H. Powell, journalist, Mexican crocodiles; Fred Hauptfuhrer, World Wildlife Fund.

Fig. 5. Adult female Orinoco Crocodile, *Crocodylus intermedius*, captured for transit to Hato Masaguaral in 1984. The crocodile shown had come close to capturing Dr. Myrna Watanabe on a visit the previous year. From left to right: three ranch-hands, Tomás Blohm, Peter Brazaitis and capture chicken, ranch-hand (rear), John Thorbjarnarson (second row, originally hired by Tomás to study Orinoco Crocodiles), ranch manager, Mark Ludlow (field researcher), ranch-hand.

Two years after the CSG was formed, a plenipotentiary meeting was held in Washington, D.C. from 12 February to 2 March 1973 just prior to the Convention on the International Trade in Endangered Species of Fauna and Flora (CITES). CITES was ratified by the United States on January 14, 1974, as did five other

countries the same year, and went into effect in the United States on 1 July 1975. The "Washington Convention" (CITES), under the United Nations Environmental Program, would provide for the regulation of commercially traded species, including virtually all crocodilians.

A framework for controlling the international trade in wildlife had been created. Enforcement in the USA would fall to the US Fish and Wildlife Service under the provisions of the US Endangered Species Act (ESA) and a host of other new and broadened national and state wildlife legislation. Although mainstream biologists might be well known for their scientific writings and research, a host of state, national, and international law enforcement officers deserve no less recognition for their role in saving crocodilians from extinction, by their efforts to halt the contraband trade in crocodilians.

The structure for enforcing and prosecuting wildlife violations called for the application of wildlife sciences to the judiciary process in a new discipline: forensic wildlife sciences (Brazaitis 1986; 1987). As the majority of crocodilian species were now protected and violations were subject to civil or criminal prosecution, crocodilians and their derivatives became the immediate focus of enforcement. The Clark R. Bavin National Fish and Wildlife Forensic Laboratory was founded in 1988 in Ashland, Oregon by the US Fish and Wildlife Service. Under the directorship of Ken Goddard, the laboratory is a state-of-the-art forensic analysis facility and the only forensic laboratory in the world dedicated entirely to solving wildlife crime.

National and international attention was focused on endangered and threatened species including crocodilians. The International Union for Conservation of Nature (IUCN), founded in 1948, published the IUCN Red Data Book to identify threatened species (Groombridge and Wright 1982). In October 1991, in Gland, Switzerland, the World Conservation Union, the United Nations Environment Programme (UNEP), and what was then called World Wildlife Fund, the World Wide Fund for Nature (WWF) joined to adopt a universal strategy of *Caring for the Earth, A Strategy for Sustainable Living*. It was a perfect fit for improving the crocodilian image, conservation, and by default—for trade as well. It was a jump-start for crocodilian sciences. The IUCN Crocodile Specialist Group would become the advisory council of world specialists to CITES and countries around the world on matters of crocodilian management and conservation.

Outstanding crocodilian conservationists.—Many people and agencies, both governmental and private, played an important role in furthering crocodilian conservation. Tomás Blohm of Caracas, Venezuela, was the recipient of the Order of the Golden Ark, created by Prince Bernhard of the Netherlands for leadership in conservation in 1971. Blohm had traditionally maintained one of his cattle ranches, *Hato Masaguaral*, in a natural state and had for many years welcomed researchers from around the world to study the endemic wildlife. Blohm and his wife Cecilia M. de Blohm set the course for the conservation movement in Venezuela.

The Orinoco Crocodile is native to the Orinoco River and its tributaries in Venezuela. The species had become all but extinct in Venezuela as a result of exploitation for the skin trade. A few adult individuals had been sequestered on the ranches of a few landowners, to protect the remaining animals. In 1984 an adult pair of Orinoco Crocodiles was transported from a hidden lagoon on property owned by Blohm adjacent to Camatagua Reservoir near Caracas, to his ranch *Hato Masaguaral* (Fig. 5), to form the nucleus of a captive group of breeding crocodiles that would eventually produce offspring to reintroduce the species in Venezuela. To date, the Venezuela program has released over 6,335 animals of which 2,475 animals were produced from the *Hato Masaguaral* program.

PHOTO BY PETER BRAZAITIS

FIG. 6. A Cuban Crocodile, *Crocodylus rhombifer,* hatches from an egg at the Bronx Zoo, New York in 1983.

John Thorbjarnarson, University of Florida and the Wildlife Conservation Society, New York, was undoubtedly the best known field biologist in crocodilian field conservation in recent times. He began his career with studies of the Orinoco Crocodile in Venezuela. As a member of the IUCN Crocodile Specialist Group and the AZA Crocodilian Advisory Group, his crocodilian interests touched on virtually every species, in captive propagation and wild populations. His field studies of crocodilian populations and natural history have produced numerous scientific and popular papers (Thorbjarnarson 1991, 1992, 1996). Perhaps one of the most valuable to international crocodilian conservation was his comprehensive paper published by IUCN in 1992. Tragically, he died on 14 February 2010, in India, at the age of 53 from acute malaria.

New directions.—If crocodilians were to be saved from extinction, crocodilian sciences had to move in new directions: behavioral, population biology, ecology, captive management and husbandry.

Probably the single most important discovery to make selective crocodilian breeding and management possible was the simplest: a method for determining the sex of crocodilians. The story is amusing. Robert Chabreck (1963) reported a manual probing method for sexing alligators that had been employed in Louisiana, in the *Proceedings of the 27th Annual Conference, Southeastern Association of Game and Fish Commission.* Separately and without knowledge of Chabreck's presentation, one of this paper's coauthors, Peter Brazaitis, had applied a similar manual probing technique that successfully determined sex in a wide range of crocodilian species at the New York Zoological Society's Bronx Zoo. However, the technique was considered too risqué for the zoo's scientific journal *Zoologica* and it was not until a number of years after the initial study was completed that

TABLE 4. Chronology of original crocodilian classification.

Year	Author	Taxon
1758	Linnaeus, Carolus (Carl von Linné)	Species: *Lacerta crocodilus* (= *Caiman crocodilus**)
1768	ibid.	Class: Reptilia
1768	ibid.	Genus: *Crocodylus*
1768	ibid.	Species: *Crocodylus niloticus*
1789	Gmelin, Johann	Order: Crocodylia
1789	ibid.	Species: *Gavialis gangeticus*
1801	Daudin, François Marie	Species: *Alligator mississippiensis*
1801	ibid.	Species: *Caiman latirostris*
1801	ibid.	Species: *Caiman yacare*
1801	Schneider, J. G.	Species: *Paleoschus trigonatus*
1801	ibid.	Species: *Crocodylus porosus*
1801	ibid.	Species: *Crocodylus siamensis*
1807	Cuvier, Georges Léopold Chrétien Frédéric Dagobert	Family: Alligatoridae
1807	ibid.	Genus: *Alligator*
1807	ibid.	Family: Crocodylidae
1807	ibid.	Subfamily: Crocodylinae
1807	ibid.	Species: *Paleosuchus palpebrosus*
1807	ibid.	Species: *Crocodylus acutus*
1807	ibid.	Species: *Crocodylus cataphractus* (= *Mecistops cataphractus**)
1807	ibid.	Species: *Crocodylus rhombifer*
1811	Oppel, M.	Genus: *Gavialis*
1819	Graves,M. L.	Species: *Crocodylus intermedius*
1825	von Spix, Johann Baptist Ritter	Genus: *Caiman*
1825	ibid.	Species: *Melanosuchus niger*
1831	Lesson, R. P.	Species: *Crocodylus palustris*
1838	Müller, S.	Genus: *Tomistoma*
1838	ibid.	Species: *Tomistoma schlegelii*
1851	Duméril, A. M. C. and Bibron, G.	Species: *Crocodylus moreletii*
1854	Adams, A.	Family: Gavialidae
1861	Cope, Edward D.	Genus: *Osteolaemus*
1861	ibid.	Species: *Osteolaemus tetraspis*
1862	Gray, J. E.	Genus: *Melanosuchus*
1862	ibid.	Genus: *Paleosuchus*
1868	Cope, Edward D.	Species: *Caiman crocodilus fuscus*
1873	Krefft, G.	Species: *Crocodylus johnsoni*
1876	Bocourt, F.	Species: *Caiman crocodilus chiapasius*
1879	Fauvel, A. A.	Species: *Alligator sinensis*
1928	Schmidt, K. P.	Species: *Crocodylus novaeguineae*
1935	ibid.	Species: *Crocodylus mindorensis*

*Name in current use.

the data were published, without zoo permission, in the *British Journal of Herpetology* (Brazaitis 1968).

Population biology.—Paramount in this new era of crocodilian conservation was determining the status of wild crocodilian populations throughout the world to investigate possible harvest quotas and to encourage investments in crocodilian conservation initiatives. It was also important to determine population characteristics and distribution limits for species. Universities, international conservation organizations, and governments rushed to comply with CITES requirements for scientific data on population levels and sustainability in order to set harvest quotas. Some pioneers were already deeply involved in crocodilian field research.

Ornithologist John James Audubon (1785–1851) and botanist/naturalist William Bartram (1739–1823) made some of the earliest observations of American Alligator natural history during their wanderings through the southern United States (Audubon 1827; Bartram 1773–1774). However, E. A McIlhenny was probably one of the first to comprehensively document the life history of a crocodilian, the American Alligator in Louisiana (McIlhenny 1935). A comprehensive bibliography of the American Alligator was published by the US Department of Energy's Savannah River Ecology Laboratory (Brisbin et al. 1986).

Robert Chabreck and Ted Joanen continued field research on alligators in the coastal marshes of Louisiana. Joanen, who directed the management of the Rockefeller Wildlife Refuge of the Louisiana Department of Wildlife and Fisheries at Grand Chenier, and the Louisiana alligator program, took the lead to ensure the survival of alligator populations in Louisiana. This work began even before national and international interest focused on endangered crocodilians and the results were used to create conservation programs. They developed strategies for the captive

propagation, wild population management, and sustainable use of alligators that remain models for crocodilian management. Joanen and his colleague at Rockefeller, Larry McNease, published more than 40 papers on the natural history and management of alligators, beginning in 1970 (Joanen 1970) to 1982 (Brisbin et al. 1986). To many, they are the fathers of crocodilian conservation, population management, and captive husbandry technology.

As in Louisiana, the Savannah River Ecology Laboratory, Aiken, South Carolina, largely supported by the United States Department of Energy, under the leadership I. Lehr Brisbin, contributed immensely to our understanding of American Alligator ecology.

The Saltwater Crocodile populations of Australia enjoyed a similar benefactor. Harry Messel, University of Sydney, Australia, and his research team surveyed all of the river systems in northern and western Australia and developed field survey techniques that became the standard for crocodilian population studies. His series of monographs (Messel et al. 1981) on the status and ecology of *C. porosus* in Australia are monumental. This legacy of crocodilian research continues today at Australian universities.

Hugh B. Cott (1961), a zoologist, wildlife photographer, and military camouflage expert, was one of the first to extensively describe the natural history and nesting ecology of Nile Crocodile (*C. niloticus*) populations in Uganda and Northern Rhodesia.

The most prolific and adventurous South American crocodilian field biologist, and incidentally, a member of the royal family of Latvia, was Féderico Medem, Instituto Roberto Franco, Colombia. His field studies and extensive publications on South American crocodilians span decades (Medem 1952, 1955, 1958a, 1958b, 1960, 1962, 1963, 1967, 1968, 1969; Medem and Marx 1955). He was the first to conduct an exhaustive field survey of the distribution of South American crocodilians under the auspices of the New York Zoological Society. However, his work was not published until years later (Medem 1981, 1983).

Probably one of the most comprehensive field surveys of crocodilians ever undertaken was initiated as a result of CITES and the need to understand the identity, distribution, and taxonomy of South American caiman. Field investigations throughout central South America were conducted by three field teams: Bolivia—led by F. Wayne King, University of Florida (King and Roca 1989); Brazil—led by Peter Brazaitis (Brazaitis et al. 1997a, 1997b, 1998); Paraguay—led by Norman Scott (Scott et al. 1988).

In China, Huang Chu-chien (Zhujian) and colleague Zheng Zuoxin, Institute of Zoology, Chinese Academy of Sciences, Beijing, studied the distribution and natural history of the Chinese Alligator in south central China in Anhui, Zhejiang, and Jiangsu provinces. They observed life habits and described its extensive cave-building behavior. Aware that the species was critically endangered in the wild, Huang was instrumental in having the Forestry Bureau in Anhui Province set up the Xuancheng Alligator Breeding Farm in southern Anhui in 1980. He was assisted by Myrna Watanabe in 1981, the first westerner to have several months' access to the region since the Communist takeover of China in 1948. Watanabe reported the population to be critically near extinction and restricted to living on tree farms and in rice paddies (Watanabe 1982). John Thorbjarnarson confirmed the Chinese Alligator's approaching extinction in 2002 (Thorbjarnarson et al. 2002; Thorbjarnarson and Wang 2010). Although thousands of Chinese Alligators currently exist on alligator farms in China, the extinction of the wild population could be imminent. The first captive reproduction of Chinese Alligators in the

United States occurred in 1977 at the Rockefeller Wildlife Refuge, Grand Chenier, Louisiana. This successful program, developed by the late John Behler at the Wildlife Conservation Society, New York, contributed to the reintroduction of US captive-bred Chinese Alligators back into the wild in 2007.

It would not be possible to provide a complete list of field biologists and students who conducted surveys of crocodilians throughout the world. Table 5 is a partial list of field biologists known for their work in crocodilian conservation, particularly those who conducted initial surveys in the 1970s and 1980s, when the population status of most species was unknown, and crocodilian behavioral science was a new concept. The University of Florida and the Florida Field Museum of Natural History, Gainesville, Florida stand out as a seat of crocodilian population ecology and biology.

Field biologists are, by definition, some of the most dedicated of scientists, often giving up a life of comfort and family relationships and living in danger. They expose themselves to tropical diseases and death to unravel the secrets of living animals in their natural worlds. They deserve great credit.

Social behavior of crocodilians.—Crocodilian behavioral studies were pioneered by a handful of scientists in the late 1970s and 1980s. Kent Vliet extensively documented the social behavior of American Alligators and other crocodilians (Vliet 1989). He is particularly noted for documenting behaviors while in the water at eye-level with alligators.

Leslie Garrick, while an intern at the Bronx Zoo, New York, documented social signals of American Crocodiles in the Dominican Republic and crocodilians at the zoo (Garrick and Lang 1977). Garrick, together with Jeffrey Lang and Harry Herzog worked on many projects (e.g., Garrick et al. 1978). Lang continued his work in India on Mugger Crocodiles and the Indian Gharial.

R. Howard Hunt, Curator of Reptiles, Zoo Atlanta, was one of the first to successfully breed crocodilians in a zoological setting and reported maternal care behavior in Morelet's Crocodiles (Hunt 1975). Hunt and Myrna Watanabe studied American Alligator behavior (Hunt and Watanabe 1982), in wild populations in Okefenokee Swamp, Georgia, and Hunt later studied crocodile behavior in Belize.

Myrna E. Watanabe, New York University, recorded and documented American and Chinese Alligator vocalizations, and was the first to observe and report nest opening and communication between mother and young, and the maternal behavior of American Alligators (*A. mississippiensis*) in Okefenokee Swamp, Georgia (Watanabe 1980). She later continued her work in China, the first in recent times, collaborating with Chinese scientists on studies involving the Chinese Alligator (*A. sinensis*).

Crocodilian husbandry science.—Three primary strategies were employed for crocodilian conservation: ranching where the wild population remained a source for eggs and young; farming where breeding animals produced offspring that could be harvested when they achieved commercial size; direct harvesting of the wild populations, or in some cases a combination of more than one (Luxmoore et al. 1985). Eventually, farming and ranching initiatives would be present in most of the nations of the world where crocodilians were endemic.

Perhaps the oldest and best known continually operated crocodile farm is the Samut Prakan Crocodile Farm, Thailand, built in 1950. In the 1970s and 1980s, Ted Joanen pioneered modern farming and ranching techniques in Louisiana that are the current basis for commercial crocodile rearing as well as for the captive propagation of endangered and threatened species in zoos. In Africa, Tony Pooley (Natal Parks Board, St Lucia, South Africa) was developing farming strategies for the Nile Crocodile (*C. niloticus*). In South Africa and Zimbabwe, crocodile farms for skins and tourism were well established, and staffers were developing nutrition and immobilization techniques for transporting large crocodiles. In Papua New Guinea, Martin Hollands was developing a model ranching program for locals.

Today, more than 80 caiman farms in Colombia annually produce more than a million crocodilian skins that find their way into the commercial exotic leather trade, mostly comprised of caiman species that may be indiscriminately hybridized. Initiatives to translocate American Alligators, Nile Crocodiles, Saltwater Crocodiles, and other species to countries outside of their natural ranges for farming have been met with disapproval by the international conservation community. Hybridization of crocodilian species to enhance leather and meat production has already threatened the genetic integrity of endangered species, such as the Siamese Crocodile (*C. siamensis*), Morelet's Crocodile (*C. moreletii*), and Cuban Crocodile (*C. rhombifer*).

The crocodilian leather industry's place in the history of crocodilian science.—In 1973, the advent of CITES created an explosion in crocodilian interest and scientific research. To understand the industry implications for crocodilian science, it is important to understand the scope of the industry (MacGregor 2002). The first level of the industry is composed of the people who harvest and produce crocodilian skins. Producers include those who hunt the wild population, and crocodile farmers and ranchers. Suppliers, buyers, and skin graders are the next level in the industry, which move skins from producers to processors. The third level is tanneries, both in and outside producing countries. Another industry supplies chemicals and machinery. A fourth level includes the people who design fashions and the manufacturers who fabricate products made from tanned skins. Last are the buyers and retailers who market products. Until CITES came into force in 1975, the industry identified crocodilian species based on skin quality, skin characteristics, and the degree of processing difficulty (Fuchs 1974a, 1974b). The industry would have to learn a new scientific-based language, crocodilian taxonomy and classification (King and Brazaitis 1971). Compliance with CITES also meant that the industry would be deprived of access to CITES-listed crocodilian species, the crocodilians that had been the mainstay of the industry, whose populations the industry depleted. It was important for the industry to support crocodilian conservation, which, in turn, supported the industry.

Industry scientists reclassified and introduced new species of crocodilians to the scientific literature, although these classifications were largely based on skins of undocumented origins, (Fuchs 1971, 1974a, 1974b; Fuchs et al. 1990; Wermuth 1986; Wermuth and Fuchs 1978; Wermuth and Mertens 1977). This caused some concern about their taxonomic validity among crocodilian scientists (Frair and Behler 1983), but the names were, nonetheless, inadvertently incorporated into CITES identification manuals (CITES, 1981, 1983) for the purposes of international law enforcement.

Some members of the crocodilian industry were instrumental in altering the course of crocodilian science. They recognized that there had to be mutual cooperation to integrate the desire of scientists to halt the abusive use of crocodilians along with the reluctance of industry to conform to new regulation. They saw a need for a new way of dealing with the reality of the diminishing resource.

FIG. 7. Male Cuban Crocodile, *Fidel*, original founder of a Cuban crocodile captive breeding dynasty, terrorizes the keeper staff during capture at the Bronx Zoo, Reptile House, New York, about 1969.

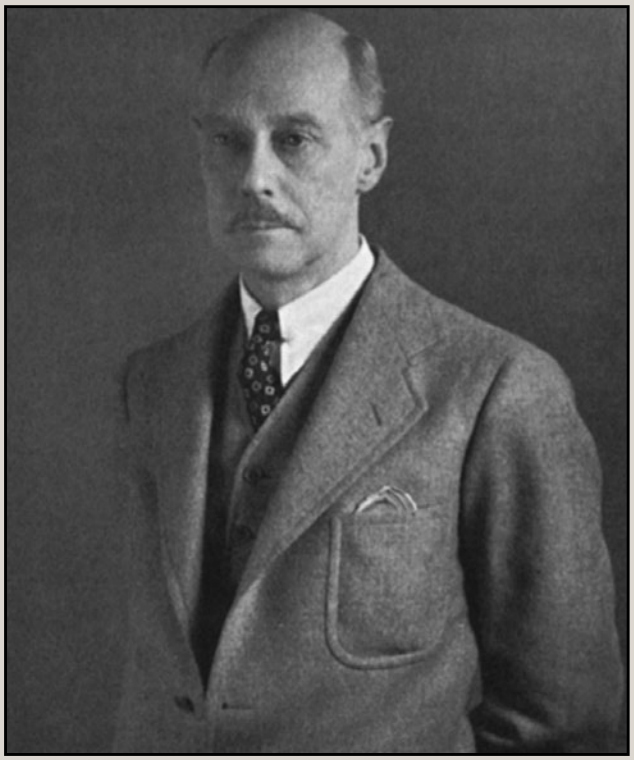

FIG. 8. Raymond L. Ditmars, first Curator of Reptiles at the Bronx Zoo, Wildlife Conservation Society, New York.

Don Ashley, a private alligator marketing consultant, recognized the economic needs of alligator farmers in Louisiana and Florida, yet urged close controls on crocodilian use in a market cleansed of illegal trade (Ashley 1979). Clare Hagan, Hagan and Co., New York, was a highly respected reptile leather product designer who immediately understood the need for change and set out to use her influence in the industry to support crocodilian and sea turtle conservation. Single-handedly, she put a stop to the use of sea turtle leathers in the fashion industry in the United States. Jay Wilson, a skin trader, assisted the IUCN CSG in making industry contacts at all levels of the trade, and helped sponsor South American students from leather-producing countries to go to US universities for education and training. Important leather tanners in the US, France, Japan, and Singapore funded population survey initiatives that would further crocodilian science, along with their own interests in procuring skins.

The AZA Crocodilian Advisory Group and international collaboration.—While international attention was focused on the development of political and national strategies for saving crocodilians and maintaining wild populations on a sustainable basis for commercial utilization, the zoological community recognized that for some species there were too few animals and sometimes no wild habitat left for sustainable populations. A small group of zoologists from some of the leading US zoological institutions met and were determined to take a hand in saving the critically endangered crocodilian species through captive breeding, starting with crocodilian collections already housed in US zoos. A Crocodilian Advisory Group (CAG) was formed and the initiative was sanctioned by the American Zoo and Aquarium Association in 1986. The CAG seeks to provide counsel on all aspects of zoo-based crocodilian conservation, and coordinates the use of available space and developing initiatives in North American zoos. The ongoing success of the AZA CAG would not be possible without the interest and commitment of David Drysdale, owner of the St. Augustine Alligator Farm, St. Augustine, Florida, and its staff.

John Behler, the late curator of reptiles at the Wildlife Conservation Society, New York, led the initiative and developed the first Species Survival Plan (Behler 1982) for a crocodilian, for the endangered Chinese Alligator. Following several unsuccessful attempts at the Bronx Zoo, Behler, Brazaitis, and Joanen, with founder stock from the Bronx Zoo and the Smithsonian National Zoological Park, Washington D.C., established the first collaborative breeding program for a crocodilian species. It stands as a model for AZA captive breeding programs for endangered species.

Colette Adams, Gladys Porter Zoo, Brownsville, Texas, led the initiative to restore Philippine Crocodiles to the wild as a result of a successful captive rearing program at the zoo. While the conservation of the Philippine Crocodile has suffered for lack of funding in the Philippines, Adams and Kent Vliet, CAG chair, are developing funding initiatives for continued captive propagation and future possible reintroduction programs.

The Bronx Zoo, New York, led the early effort to develop captive breeding technology beginning in the mid-1970s. Nine species of crocodilians, including critically endangered Cuban Crocodiles (Fig. 6), Siamese Crocodiles in 1983, and the first captive breeding of the endangered Malayan False Gharial (*Tomistoma schlegelii*) in 1985 in a North American Zoo (Brazaitis and Abene 2008). However, typically, "first breedings" are only a precursor to future successes as technology and husbandry improve and are tailored to the needs of individual animals and species. A pugnacious nature made Cuban Crocodiles particularly

difficult to manage (Fig. 7); juvenile Philippine Crocodiles were found to be totally intolerant, even to each other (Colette Adams, pers. comm.). Breeding of the Malayan False Gharial has now been successful in the private collection of AZA member Bruce Schwedick, and additional captive breeding facilities have been developed at the Virginia Aquarium, Virginia Beach, Virginia.

A global crocodilian community.—Crocodilians were already a subject of interest 100 yrs BC (Grant 1992). Private and zoological collections of crocodilians have existed in many parts of the world (Flower 1937; Honegger and Zeigler 1991; Trutnau and Sommerlad 2006).

The Atagawa Tropical & Alligator Garden in Japan, opened free to the public in 1958, conducted crocodilian breeding research and provided breeding stocks of crocodilians to zoos throughout the world.

The Samut Prakan Province crocodile farm in Thailand opened in 1950 and now houses over 60,000 crocodiles. The farm is a favorite tourist attraction, has published articles on crocodile biology and husbandry, and produces thousands of skins for the exotic leather trade.

The Madras Crocodile Bank Trust, in the state of Tamil Nadu, India, was established in 1976 as the idea of Romulus and Zai Whitaker. The mission of the Trust is to save India's three crocodile species, the Mugger Crocodile, Saltwater Crocodile, and the nearly extinct Indian Gharial.

Crocodile farms exist today throughout the world, in all of the warmer and temperate regions. Commercial husbandry practices were being developed in Australia, South Africa and Zimbabwe prior to the 1971 meeting of the crocodile specialists in New York.

The European zoological community has a long and venerable history involving crocodilian science. The European crocodilian community is part of the EAZA (European Association of Zoos and Aquaria) developing crocodilian captive breeding initiatives similar to those of the AZA CAG. As of 2008, 52 institutions, holding 147 animals, took part in a coordinated Dwarf Crocodile (*Osteolaemus tetraspis*) captive breeding effort that includes the latest in genetic modeling. A second program for the Malayan False Gavial is in development. Ongoing successful programs also include *Crocodylus johnsoni* at Frankfurt Zoo, with 100 offspring produced; a *C. mindorensis* program in development at the Chester, UK zoo; and *Mecistops cataphractus* at the Emmen Zoo, Holland, with more than 100 offspring produced (R. Sommerlad, pers. comm.).

Crocodiles not bad—crocodiles good!—The history of crocodilian science would be incomplete without calling attention to the importance of public awareness of crocodilians. While scientists studied the skulls and skins of crocodilians from the remote regions of the world in the obscure collections of museums and universities, the general public wanted to see and hear about these sometimes immense and terrifying creatures that obviously were related to mythical dragons and dinosaurs, and ate people if they could. This public interest came to the rescue of crocodilians worldwide when crocodilians needed attention most—at the brink of extinction.

Historically, nearly every zoo exhibited at least one crocodile or alligator, the bigger the better. Raymond L. Ditmars (Fig. 8) was curator of reptiles at the New York Zoological Park, New York, from 1899 until his death in 1942. He recognized the scientific value and visitor interest held by crocodilians (DeSola 1933; Ditmars 1913) and made the zoo's crocodilian collection (Fig. 9) one of the most important and well known at the time (Brazaitis and Abene

2008) through his popular and scientific publications. The legacy of Ditmars continues today through the work of the AZA CAG.

More than one private entrepreneur has made a living separating the curious from their money by offering a peek at "the biggest alligator in the world" for a small fee. The St Augustine Alligator Farm was never a farm for alligators but began as a tourist attraction that exhibited great numbers of American Alligators (Adams and Shiver 1993). Established in 1893, it continues to thrill and educate thousands of visitors from around the world. The "Alligator Farm" as it is locally called, became an accredited member of AZA in 1989 and under the ownership of David Drysdale, has become a pre-eminent center for crocodilian research and the captive breeding of endangered crocodilian species. It is the only institution in the United States to be dedicated entirely to crocodilian sciences and to exhibit all 23 recognized species of crocodilians.

E. Ross Allen was another early entrepreneur. He founded Ross Allen's Reptile Institute in Silver Springs, Florida, in 1929. The Institute exhibited a variety of crocodilians and other reptiles, and featured the role of the American Alligator in the life and culture of Native Americans. Allen died on May 17, 1981 at the age of 73, before realizing his dream of establishing "Alligator Town," dedicated to the preservation of the American Alligator.

Bruce Schwedick, a member of the AZA Crocodilian Advisory Group and a wildlife educator, pioneered mobile educational programs (Reptile Discovery Programs, Plant City, Florida) that take endangered species of reptiles, including crocodilians, to schools and audiences throughout the United States. As the U.S. representative to the international *Tomistoma* Task Force, he invests considerable time and personal funds to the conservation of endangered crocodilians.

In recent times, perhaps no other person has brought crocodilians to the attention of the public through the medium of worldwide television than Steve Irwin, best known as "The Crocodile Hunter." His television series reached millions of viewers around the world on nearly a daily basis. He and his wife Terri coowned and operated the Australia Zoo in Beerwah, Queensland, featuring Australian crocodilians and conservation. Irwin died on 4 September 2006 after being fatally stung by a stingray. Adam Britton, an Australian scientist, continues the effort to bring crocodilian science and education to the public forefront. There are many other private individuals who, in their own way, contribute immensely to the development of crocodilian sciences.

Many popular writers have contributed to crocodilian literature and science. Among the best known are Raymond L. Ditmars and Ralf De Sola of the then-New York Zoological Society (Ditmars 1913; DeSola, 1933), Wilfred T. Neill (Neill 1971), and C. A. W. Guggisberg (Guggisberg 1972).

It is fitting that this preliminary history of crocodilian science should end with illustrations of the precursor of the St. Augustine Alligator Farm as it appeared in 1890 (Fig. 10) and 120 years later (Fig. 11), spanning the period when crocodilian science has made some of its greatest advances.

Acknowledgments.—We acknowledge and thank David Drysdale, John Brueggen, Kevin Torregrosa, and the entire staff of the St. Augustine Alligator Farm for their support and continued interest in crocodilian sciences, the Association of Zoos and Aquariums, the AZA Crocodilian Advisory Group and its board of Directors, Kent Vliet, and especially the many zoological institutions that have taken part in furthering the science of crocodilian management. Thanks to James B. Murphy for his interest in historical manuscripts and the preservation of herpetological history. Thanks to the Yale Peabody Museum of Natural History, Division of Vertebrate Zoology , and the Wildlife Conservation Society, Department of Reptiles and Amphibians, and its staff, past and present. Thanks to Myrna Watanabe, for her patience and interest, and for reading very many manuscripts.

Dewlap Coloration of Some Species of Anoles from Venezuela

One of the most conspicuous characteristics of anoles (genus *Anolis*) is the presence of an extensible and often colorful dewlap or throat fan, which these lizards extend during territorial or sexual displays. The dewlap is always conspicuous in males (reduced in only a couple of species), and is slightly smaller to rudimentary in females. Coloration, size, and squamation of the dewlap are often species-specific and of high diagnostic value. Illustrated here are the dewlaps of eleven of the 24 currently known species of Venezuelan anoles: 1) *Anolis tropidogaster* male, 2) *Anolis fuscoauratus* male, 3) *Anolis chrysolepis planiceps* male, from localities on northcentral and northwestern Venezuela, 4) *Anolis chrysolepis planiceps* male, from localities on southern Venezuela, 5) *Anolis auratus* male, 6) *Anolis chrysolepis scypheus* male, 7) *Anolis onca* male, 8) *Anolis tigrinus* male (left) and female (right), 9) *Anolis euskalerriari* male, 10) *Anolis anatoloros* male (left) and female (right), 11) *Anolis jacare* male (left) and female (right), 12) *Anolis punctatus* male, 13) *Anolis squamulatus* male.

Gabriel N. Ugueto is a graphic designer, illustrator, and herpetologist born in Venezuela, but he has resided in Miami, Florida, since 1999. He has worked for the past eight years on the systematics and taxonomy of the South American herpetofauna. Currently, Gabriel's main interests are the systematics of Teiidae, *Anolis, Polychrus, Phyllodactylus,* and the herpetofauna of the Venezuelan islands in the southern Caribbean. His recent publications have appeared in *Caribbean Journal of Science, Zootaxa, Herpetological Review,* and *Herpetological Monographs* and include descriptions of several new species and taxonomic revisions. Additionally, he is the senior author of *Amphibians and Reptiles of Margarita, Coche and Cubagua*, Edition Chimaira, 2010. His illustrations appear in his own publications and those of several colleagues. Recently, his illustrations of lizards were published in *Libro Rojo de La Fauna Venezolana.*

Gabriel prepared this panel of Venezuelan anoles using a mixed technique that includes crayons, watercolor, and gouache. Each illustration was based on color photographs or direct observation of live specimens. The illustrations were then scanned and final touches were added digitally. Some of his scientific illustrations can be viewed at http://kana-hebi.deviantart.com

**Deutsche Gesellschaft für Herpetologie und Terrarienkunde, Postfach 1421, 53351 Rheinbach, Germany*
e-mail: gs@dght.de

The DGHT, German Society for Herpetology and Herpetoculture ("Deutsche Gesellschaft für Herpetologie und Terrarienkunde e.V.," www.salamandra-journal.com, www.dght.de), was founded in 1964 as a successor of the German herp group "Salamander" going back to the year 1918. One of the founders of DGHT was the famous German herpetologist Robert Mertens. As implied by its name, DGHT philosophy is to bring together professional scientists and amateurs, thus promoting their dialog at an international scale. This gives the society a unique strength currently uniting more than 7,000 members including several, in herpetology, internationally well acknowledged honorary members.

The society's mission is to contribute to both research on amphibians and reptiles and captive keeping and breeding. DGHT is strongly engaged in herpetological conservation and is accredited by the German Federal Nature Conservation Act. The society runs three funds: the Wilhelm Peters Fund dedicated to herpetological research, the Hans Schiemenz Fund attributed to assessing and protecting natural populations of amphibians and reptiles, and, in collaboration with the Zoological Society for the Conservation of Species and Populations (www.zgap.de), a fund supporting conservation activities to protect threatened amphibian and reptile species.

FIG. 1. *Mertensiella* focuses on special topics such as varanid lizard research (Advances in Monitor Research I and II, published in 1991 and 1999, respectively).

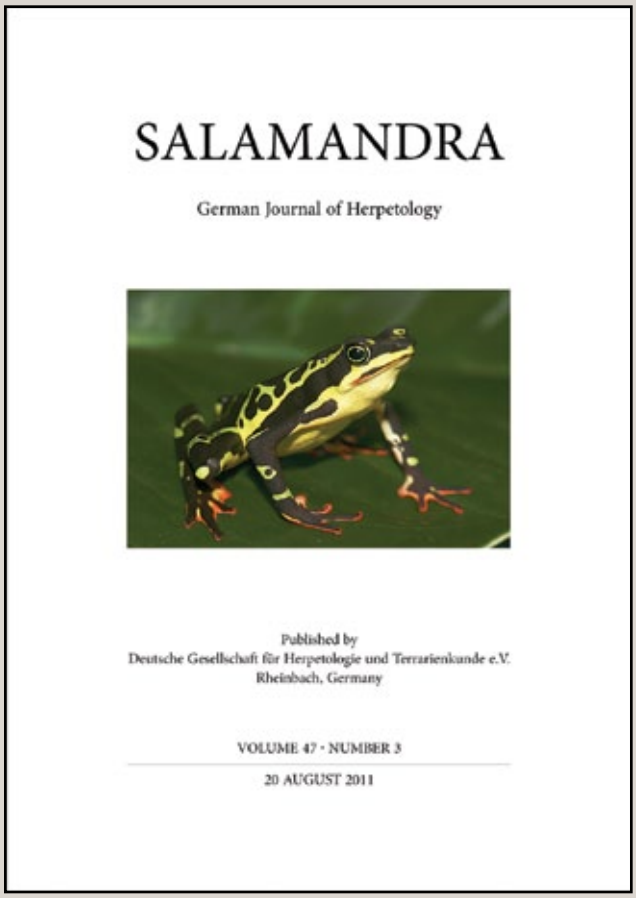

FIG. 2. *Salamandra* is the society's flagship scientific journal, published exclusively in English, covering broad range of topics, including systematics, ethology, ecology, and conservation biology.

Since the "Year of the Frog 2008," DGHT, in cooperation with the Association of German Zoo Directors (www.zoodirektoren.de), is involved in amphibian ex situ conservation efforts. Our activities especially unit conservation breeding projects run in Austria, Germany, and Switzerland and aims at a joint venture of zoos and private keepers. One of the target species is the critically endangered CITES Appendix 1 newt, *Neurergus kaiseri* (Luristan Newt), with currently more than 3,000 individuals, 85% of which are captive-bred.

DGHT is divided into more than 50 subgroups; besides local and regional branches in Germany, Austria, and Switzerland, there are working groups which put particular focus on different herps (e.g., anurans or chelonians), special topics (e.g., history of herpetology, veterinary science), or even more specialized on particular taxa (e.g., chameleons). Subgroups have their own meetings independent from the annual international meetings of the society combining herpetological science ("Deutscher Herpetologentag") and herpetoculturism, including herp travel reports, conservation, captive breeding, etc. ("DGHT-Nachzuchttagung"). Note that in September 2011, DGHT for the first time held a joint scientific meeting with Societas Europaea Herpetologica, SEH (www.seh-herpetology.org), the European herpetological society, at Luxembourg.

Among the print media of DGHT are *Salamandra—German Journal of Herpetology*, a quarterly journal publishing scientific contributions in English in all fields of herpetology, listed under Current Contents and soon under the Science Citation Index (available online), *Mertensiella*, a sporadically published supplement with special issues on particular topics (e.g., symposium volumes), *elaphe*, a colored quarterly German magazine reporting on different aspects of herpetology and herpetoculture, as well as internal political issues of DGHT. Furthermore, most of the working groups publish additional separate journals, e.g., *Radiata* (with English and German editions) (Figs. 1–4).

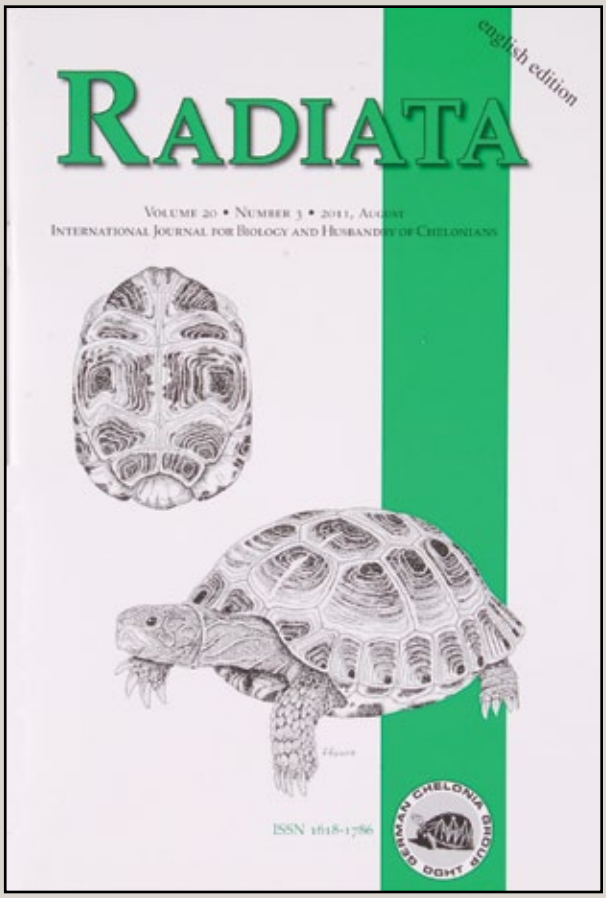

FIG. 3. *Radiata* focuses on the natural history, herpetoculture, and conservation of turtles and tortoises, and is published in German and English.

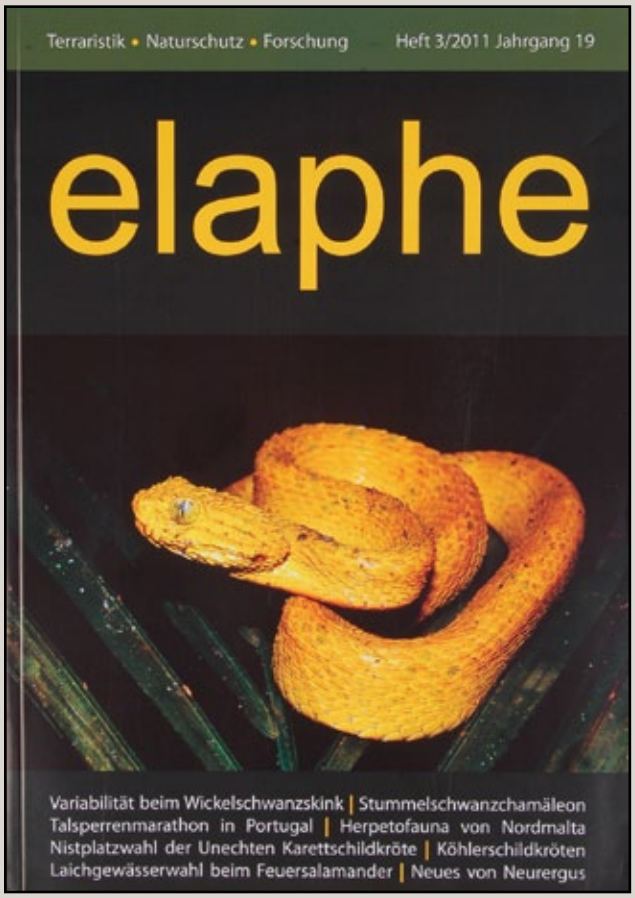

FIG. 4. The German language quarterly *elaphe* covers herpetology and herpetoculture, as well as news and information about the DGHT.

Comment on the Conservation Status of the Desert Tortoise(s)

PHOTO BY JASON FOLT

FIG. 1. Adult *Gopherus morafkai* at burrow entrance, Maricopa County, Arizona, October 2010.

PHOTO BY TODD PIERSON

FIG. 2. *Gopherus morafkai*, Pima County, Arizona, August 2011.

Murphy et al. (2011) proposed that the Desert Tortoise (*Gopherus agassizii*) be split into two separate species. As suggested by their title, the authors made a significant effort to disentangle a dizzying array of confusion surrounding the taxonomy of the species. They elevated populations south and east of the Colorado River in Arizona and Mexico to species level and named them *Gopherus morafkai*, with tortoises north and west of the Colorado River retaining the name *Gopherus agassizii* (Figs. 1–4). Currently, *G. agassizii* (*sensu stricto*) is listed as Threatened under the U.S. Endangered Species Act (ESA), with the listed entity defined as a distinct population segment (Mojave population) of the larger species (*sensu lato*; USFWS 1990, 2010a). The Sonoran population segment (*G. morafkai*) was determined to be warranted for listing under the ESA, but precluded by higher priorities (USFWS 2010b). The boundaries and genetic basis for the species delineation proposed by Murphy et al. (2011) and the population designations recognized under the ESA are completely analogous, both divided precisely along the Colorado River.

After describing their taxonomic investigation, Murphy et al. (2011) comment on implications for conservation as a result of the proposed new species recognition, which would reduce the geographic range of *G. agassizii* to about 30% of its previously recognized range. These comments include several statements that are misleading or factually incorrect, which I wish to clarify here. Specifically, the paper's authors claim that "[t]he most important implication of describing *G. morafkai* is that Arizona and Mexico can no longer be considered to harbor a genetic reservoir for the Mojavian population of the desert tortoise" (and *vice versa*) and that the reduced range of *G. agassizii* indicates that the species may more appropriately be classified as Endangered, rather than Threatened.

ROY C. AVERILL-MURRAY
U.S. Fish and Wildlife Service, Desert Tortoise Recovery Office
1340 Financial Boulevard, #234, Reno, Nevada 89502, USA
e-mail: roy_averill-murray@fws.gov

The first claim, that each species can no longer be considered a genetic reservoir for the other, is based on a premise with no historical basis, that tortoises on either side of the Colorado River were ever considered genetic reservoirs for one another. Recognition of genetic differences between the two populations/species of Desert Tortoises predates the listing of the Mojave population in 1990 (Jennings 1985; Lamb et al. 1989). Nothing in the listing rule, original recovery plan, or revised recovery plan suggest reliance upon the opposite population as a genetic reservoir. The final listing rule for the Mojave population recognized that the Colorado River "has been an effective geographic barrier, separating the Mojave and the Sonoran populations for millions of years" (USFWS 1990). The original recovery plan specifically recognized the importance of genetic differentiation in its recommendation that genetically homogeneous populations should be the sole basis for any research into translocations of Desert Tortoises (USFWS 1994). The revised recovery plan places greater emphasis on the use of experimental population augmentation as a recovery strategy, but it also specifically mentions the need to consider genetics in such a program (USFWS 2011). In summary, neither population/species has been considered a genetic reservoir for the other in Desert Tortoise management history.

The second claim, that the reduction in range of *G. agassizii* (*sensu stricto*) warrants species classification as Endangered, also ignores regulatory history. As noted above, the Fish and Wildlife Service recognized the distinction between the Mojave and Sonoran populations at the time the Mojave population was listed as Threatened. The status determination for the Mojave population of the Desert Tortoise was based on a threats analysis specific to that population (USFWS 1990; see also USFWS 2010a). Consideration of—or even the existence of—tortoises on the opposite side of the Colorado River played no part in determining that the Mojave population should be classified as Threatened, rather than Endangered. Likewise, the status determination for the Sonoran population was independent of the status, abundance, or existence of the Mojave population (USFWS 2010b). Taxonomic elevation of the Sonoran population to a full species has no effect on the Federal regulatory status of either species.

While Murphy et al. (2011) may have clarified long-standing confusion surrounding the taxonomy of the Desert Tortoise, clarifying the confusion their paper created about the conservation of the species is more than just an esoteric exercise. Press releases associated with the release of this paper generated a significant amount of media attention and public exposure about the new species and their supposed status (e.g., Center for Biological Diversity 2011; Danelski 2011). Incorrect public perception about how the proposed taxonomic change affects the species' status can only undermine the effectiveness of the ESA. Overstating a species' degree of endangerment, or otherwise misrepresenting important considerations relative to the species' status, opens the door to accusations by critics of the ESA of the distortion of science to serve ulterior, advocacy-based motives. On the other hand, setting unwarranted public expectations that new listing designations or regulatory changes should be forthcoming is destined to cause disillusionment among ESA proponents about the Act's effectiveness. Neither scenario serves the conservation purposes of the ESA.

Whether or not one agrees with the current official status designations of *G. agasszii* or *G. morafkai* under the ESA, tortoises on both sides of the Colorado River are recognized to be suffering from population declines. Conservation efforts are appropriately focused on factors contributing to these declines and on factors inhibiting the species' ability to maintain self-sustaining populations. Exaggerated claims of species imperilment distract from this focus.

Acknowledgments.—I thank L. Allison, C. Darst, K. Field, and C. Mullen for providing helpful comments to improve readability of the manuscript. The findings and conclusions in this article are those of the author and do not necessarily represent the views of the U.S. Fish and Wildlife Service.

Natural History Notes on the Ecology and Conservation Status of the Honduran Endemic Frog *Isthmohyla insolita* (Anura: Hylidae)

The Honduran endemic frog *Isthmohyla insolita* (McCranie, Wilson, and Williams; Fig. 1) was previously known to occur only at its type locality (McCranie and Wilson 2002), a small stream in primary forest at 1550 m elevation in the Cerro Texíguat Wildlife Refuge in the Cordillera Nombre de Dios of north-central Honduras. Egg masses of this species have been found on vegetation overhanging the stream and males were reported to attend single egg masses at night (Wilson et al. 1994; Fig. 2). During 2–6 September 2003, we visited the type locality of *I. insolita* to determine its population status. Herein we report *I. insolita* from a second nearby stream and include information on spatial distribution of its nests, behavior of a male guarding an egg mass, and an apparent population decline of the species at the type locality.

The second *Isthmohyla insolita* locality (15.4305°N, 87.3089°W) is a small stream at 1690 m elevation that is covered by secondary growth vegetation, consisting mainly of bushes 1–3 m in height and some scattered trees attaining heights of about 5 m. Apparently a landslide destroyed the original forest because for about 10–20 m on either side of the stream there is little soil and leaf litter and the ground is littered with rocks, logs, large fallen trees, and other debris apparently carried down by the landslide. The stream was about 50 cm wide and about 30 cm deep at its deepest point in the area we worked. The immediate area above the landslide supports moderately disturbed broadleaf cloud forest (Lower Montane Wet Forest formation, Holdridge 1967). The vegetation structure at the second locality differs significantly from the complex forest structure and high plant diversity at the type locality stream. In addition, the second stream is considerably smaller than the type locality stream, where an average width of about 3 m and a depth of about 1 m occurred in many places during September 2003. This new locality is about 0.5 km N of the species' type locality.

On 4 September 2003, we heard several male *Isthmohyla insolita* calling near this new locality stream. Males began calling at 1845 h (about 15 min before dark) from vegetation overhanging the stream. One egg mass and one male were located and two other males were calling along the same section of the stream. These males were still calling when we left the site at about 1950 h.

During the day of 5 September 2003, we searched for egg masses in about a 150 m transect along the new locality stream. We found five *Isthmohyla insolita* egg masses (not collected). The five egg masses contained 47–76 (mean = 62.0 ± 11.7) eggs and were 1.5–3.4 m (mean = 2.6 ± 0.96) above the water. Wilson et al. (1994) reported that six *I. insolita* nests contained 23–44 (mean = 33.8 ± 8.5) eggs at the type locality stream in primary forest. The number of eggs per nest was significantly greater in the disturbed habitat than in primary forest ($t = 4.61$, $p = 0.001$, $df = 9$). The significance of the higher egg numbers in the nests found in the disturbed habitat at the new locality is unknown, but we stress that our results are restrained by the lack of multiple site analyses. All egg clutches were placed on the upper surface of leaves directly over the water. Four of the five nests found in 2003 were exposed to direct sun light, at least during some hours of the day. *Isthmohyla insolita* probably breeds throughout the rainy season as we found egg masses in the process of hatching, as well as recently laid egg masses.

Also during the day of 5 September, we located an adult male *Isthmohyla insolita* near one of the egg masses mentioned above. The frog was apparently sleeping 1.2 m above the water, with the egg mass suspended 2.0 m above the male's daytime retreat and on a different plant. The frog was perched in a head up position on the vertical stem of a small plant. On the afternoon of 6 September, the frog was in the same place and position as the previous day. We waited nearby for dark and recorded its behavior from 1735 to 1914 h. The frog began slow movements towards the egg mass at 1740 h until it reached a point about 2 cm from the eggs at 1833 h. After its first initial movement of about 1 cm, the frog began an alternating series of face rubbing (with alternating movements of its hands) and push-ups that lasted about 6 min. These actions were followed by a series of yawns that lasted about 3 min. The frog then varied its movements between remaining motionless, short jumps, and short walking movements until it reached its perch site near the eggs.

At 1835 h, the frog hit the leaf five times (about one hit per second) with its left hand. Each hit was strong enough to agitate the eggs in the mass. The frog remained motionless in that position until the end of the observation period at 1914 h (neither the frog nor the eggs were collected due to concerns about the species' population status).

There is a considerable diversity of parental care known in anurans, but attendance of arboreal eggs placed above streams is rare in the Neotropics. The best-known example of this type of behavior is that of the centrolenid genus *Hyalinobatrachium* and in some species of that genus this behavior is related to hydric brooding and guarding the eggs from predators (Duellman and Trueb 1986; Savage 2002). The attendance of terrestrial nests by salamanders is related to mechanical agitation of the eggs and is thought to serve the purpose of aeration and prevention of adhesions (Duellman and Trueb 1986; Bruce 1998). The behavior observed in *Isthmohyla insolita* does not appear to be related to hydric brooding, but at least one of the observed frog's actions could be described as mechanical agitation of the eggs. Longer periods of observation are needed to decipher the purpose and benefits of this complex behavior.

During the period of 2–6 September 2003, we walked three nights for about 3 h each (from about 1800 to 2100 h) along the stream at the type locality of *Isthmohyla insolita*. We did not find nests or adults of *I. insolita* along this stream, and heard only two males calling the first two nights. Thus, the abundance of *I. insolita* at that time appeared to be lower at its type locality than that observed during the previous visits to the stream in 1991, 1993, and 1995. The reason for this apparent decline might be related to the availability of nesting sites. During October 1998, Hurricane Mitch caused severe flooding in this region of Honduras. Rivers draining the southern flanks of the mountains in which the *I. insolita* localities lie, now flow in central channels among wide boulder fields devoid of vegetation. Such damage was also evident along the *I. insolita* type locality stream during 2003. On the second author's previous visits to the locality, there was abundant leafy vegetation and moss covered tree branches overhanging the stream that were being used as nesting sites by *I. insolita* (see Wilson et al. 1994; McCranie and Wilson 2002). However, during September 2003, there was very little vegetation overhanging the stream and moss covered branches above the stream were absent. Thus, nesting sites were either unavailable or limited in scope at that time and might have been the reason for the few frogs along this stream at that time. However, complicating this scenario is that between 1993 and 1995 declines in other streamside frogs apparently occurred along this stream (McCranie and Wilson 2002). During August 1991 and July–August 1993, the hylid frogs *Plectrohyla guatemalensis* and *Ptychohyla spinipollex* and the craugastorid frogs *Craugastor aurilegulus* and *C. stadelmani* were frequently seen along this stream. However, during July 1995, *Ptychohyla spinipollex* was present in reduced numbers, but the other three frog species could not be found despite a concerted effort to do so. *Isthmohyla insolita* remained common at the site during July 1995, so the factors causing the decline of the other species did not appear to be affecting the *I. insolita* population at that time. During September 2003, *Ptychohyla spinipollex* remained in low population densities at the type locality stream, but was not found at the second stream. The other three species of frogs still could not be found in September 2003 at the former stream or at the second stream. The survey methods and number of man hours spent were similar in all visits to the locality.

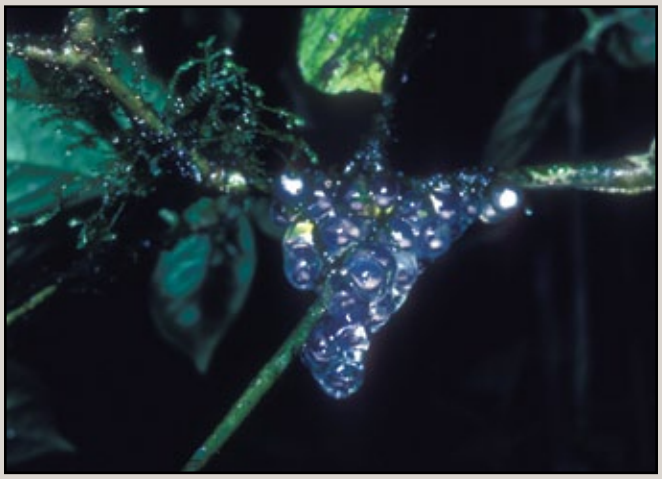

FIG. 2. Egg mass (USNM 330202) of *Isthmohyla insolita* from its type locality.

McCranie and Wilson (2002) used an Environmental Vulnerability Gauge in an effort to identify species that were most vulnerable to population declines. The higher the score for a given species, the more likely it is for that species to be vulnerable. *Isthmohyla insolita* scored a 15, just below the highest attained score (16). Wilson and McCranie (2003a, 2003b) modified that gauge with the highest attained score becoming 17. *Isthmohyla*

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

insolita scored 16 in that revised gauge. Thus, it is evident that continued monitoring of this species and additional natural history studies are urgently needed.

Acknowledgments.—We are grateful to G. Enamorado and his family in the village of San Francisco, Yoro, for their help in getting us to Texíguat, to H. Portillo, M. Moreno, and C. González of AFE-COHDEFOR (Tegucigalpa) for issuing the collecting permits, and to the late F. D. Castañeda for providing a vehicle.

Live Fast, Die Young? A Six-Year Field Study of Longevity and Survivorship in Blanchard's Cricket Frog (*Acris crepitans blanchardi*)

Tetrapods typically have overlapping generations and are long-lived organisms; however, some remarkable exceptions to this pattern are known. For example, Karsten et al. (2008) recently documented a chameleon from Madagascar with a post-embryonic life span of only 4–5 months. Among frogs, a recent review of the literature found that some species can be quite long-lived under natural conditions, especially in the temperate zone (up to 37 years; Bell and Pledger 2010; Wells 2007). Relatively small-bodied species tend to have shorter life spans (~ 3–5 years). For example, Spring Peepers (*Pseudacris crucifer*) have been estimated with skeletochronology to survive a maximum of four or five years (Lykens and Forester 1987; Zimmitti 1999) and typically begin breeding in their third spring (as two year olds). In contrast, a number of tropical frogs are known to be short-lived (1–2 years; e.g., Galatti 1992; Kluge 1981; Lehtinen 2009; Ramirez et al. 1998). However, in environments with little seasonality, much of the year is presumably suitable for activity, permitting rapid growth and attainment of reproductive maturity. Thus, the apparent greater longevity of temperate frogs may in part reflect the reduced opportunities for growth and the necessity of dormancy during unsuitable times of the year.

One temperate frog species that is thought to have a very short life span is Blanchard's Cricket Frog (*Acris crepitans blanchardi*). Pyburn (1961) provided the first evidence of a short lifespan when he reported fall breeding populations in Texas that consisted almost entirely of known young of the year (see also Pyburn 1958). Similarly, Bayless (1969) found evidence of fast growth rates in Blanchard's cricket frogs, such that metamorphs could likely grow to reproductive maturity and breed within the same year they metamorphosed. Burkett (1984) captured over 3500 individuals in populations near Lawrence, Kansas and estimated that the average lifespan was only 4 months with complete population turnover occurring in approximately 16 months. More recently, McCallum et al. (2011) summarized data on the seasonal distribution of body sizes which also was suggestive of rapid growth and a short life span. Thus, a number of previous studies have been suggestive of a short life span in Blanchard's Cricket Frogs, yet none of these studies was explicitly focused on the determination of longevity and most were of relatively short duration. Given that an annual life history in a temperate frog would be highly unusual, additional confirmatory data are needed. This is particularly important at present, as this species is thought to be in decline over much of the northern portion of its range (Gray et al. 2005; Lannoo 1998; Lehtinen 2002; Lehtinen and Skinner 2006). Here, we use individual recapture histories and seasonal variation in body size from a six-year field study to provide data on longevity of this species under natural conditions.

Methods.—The study site consisted of seven ponds at or adjacent to St. Marys Fish Hatchery in Grand Lake St. Marys, Auglaize County, Ohio, USA (40.517°N, 84.417°W). Twenty-six site visits spanned 2004–2009 (Table 1) where from one to eight persons attempted to capture all post-metamorphic (or nearly metamorphosed) Blanchard's Cricket Frogs encountered. Most site visits occurred during daylight hours and frogs were captured by hand with the assistance of dip nets. We focused our sampling activity along the pond margins, where cricket frog activity is concentrated (Burdick and Swanson 2010; Martinez-Ortiz 2004; Pyburn

1958; Smith et al. 2003) but also regularly checked adjacent grassland and woodland habitats. Ponds were sampled by walking in a single direction around the pond to avoid recapturing recently marked individuals (and thus artificially inflating recapture rates). All captured individuals were sexed externally (by the presence of breeding coloration in the throat of males - this was only possible during the breeding season) and measured (snout-vent length, SVL) using Mititoyo SC-6 digital calipers to the nearest 0.1 mm. All captured individuals were classified into one of three size categories: adult (≥ 23 mm SVL), subadult (17–22 mm SVL) and metamorph (10–16 mm SVL). These categories were based on the size at which we first observed secondary sexual characteristics and the observed range of sizes at metamorphosis (individuals with the tail not yet fully resorbed). This population of Blanchard's cricket frogs has tested positive twice for the fungal pathogen *Batrachochytrium dendrobatidis* (hereafter *Bd*): once in 1999 (see Zippel and Tabaka 2008) and again in 2006 (Steiner and Lehtinen 2008).

From 2004 to 2007, all captured cricket frogs received a year-specific toe clip (one toe only) to indicate the year in which they were first marked such that a minimum known lifespan could be established for recaptured individuals. Toes were clipped using scissors, which were sterilized with 95% ethanol after each use (Ferner 2007). In 2008, we more intensively sampled this population and used visual implant elastomer (VIE, Northwest Marine Technology Inc., Shaw Island, Washington, USA) to give individual marks to each adult captured. Only adults were marked in 2008 and 2009 as we sought to more rigorously assess both within-season mortality and inter-annual survival in adults. This method was used in favor of using multiple toe clips to uniquely mark individuals because some research has suggested that clipping more than one toe can decrease survival (McCarthy and Parris 2001, 2004). Two colors of elastomer were used (fluorescent pink and orange). Six ventral body locations were used as elastomer injection sites (upper arms and upper and lower legs) using 0.3-cc syringes. A deep-violet flashlight (λ = 405 nm) was used to aid in the detection of elastomer marks if the marks could not initially be detected under ambient light. In 2009, site visits were concentrated in May and June to attempt to recapture adults marked in the previous breeding season.

Kruskal-Wallis tests were used to test for significant differences in SVL among months (data pooled for all years). Sequential Mann-Whitney tests were then used as post-hoc tests to identify which groups differed significantly from one another. For these comparisons, the level of significance was adjusted with the Bonferroni procedure (α = 0.0033). Parametric procedures could not be used with the SVL data as test assumptions were strongly violated. An independent-samples *t*-test (assumptions checked using Kolmogorov-Smirnov, Shapiro-Wilk and Levene tests) was used to assess sexual size dimorphism in adults. Too few recaptures were obtained to estimate population sizes; therefore, we examined trends in abundance with a linear regression of catch-per-unit-effort (number of frogs captured per person-hour of sampling effort) versus time. Because of the goals of the study and the nature of the resulting data (see Results), longevity estimates were estimated empirically from recaptured individuals; we did not employ capture-mark-recapture models.

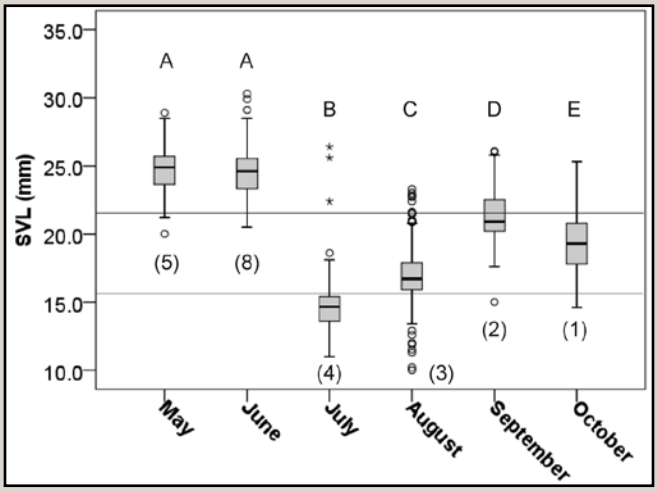

FIG. 1. Boxplot of cricket frog SVL versus month of collection (N = 961). Each box represents 50% of cases; the line across the box is the median value. The whiskers extending from each box represent the minimum and maximum values for that month (circles are outliers, asterisks are extreme outliers). Months that share letters above the boxes are not significantly different. The solid horizontal lines indicate the approximate boundary between metamorph and juvenile body size (below) and juvenile and adult body size (above). The number of site visits in each month is given in parentheses below each box. Note that body size data in this figure is pooled over all years and therefore mixes data from multiple cohorts together.

TABLE 1. Summary of 2004–2009 mark-recapture data from *Acris crepitans blanchardi*. CPUE = catch per unit effort (# frogs captured per person-hour of effort).

				Recaptures						
Year Marked	# Site Visits	CPUE	# Marked	2004	2005	2006	2007	2008	2009	Between-year Recapture Rate
Adults, subadults, and metamorphs marked										
2004	3	12.0	564	3	2	0	0	0	0	0.004
2005	5	2.5	64	-	0	0	0	0	0	0.000
2006	3	5.1	116	-	-	1	2	0	0	0.017
2007	3	1.9	51	-	-	-	2	3	0	0.059
Only adults marked										
2008	10	1.9	125	-	-	-	-	38	0	0.000
2009	2	10.5	41	-	-	-	-	-	0	0.000

Results and Discussion.—Previous studies have suggested that Blanchard's cricket frogs grow and attain sexual maturity quickly and have a short life-span (e.g., Bayless 1969; Burkett 1984; Pyburn 1961). However, all of these prior studies were relatively short-term (< 1–3 years) and most were conducted in southern portions of the geographic range. This left open the possibility that a longer-term study or one in a more strongly temperate climate might reveal different patterns. On the contrary, our data confirmed the patterns previously documented. A total of 961 individuals were captured and marked over the course of our study. Of these, 51 were recaptured (5.3% recapture rate, including individuals recaptured multiple times; Table 1). Forty-four of the recaptures occurred within the year the individual was initially marked (86%). The remaining seven recaptures (14% of total, Table 1) were all originally marked in the previous year. No individuals were recaptured that had been marked two or more years previously. The seven inter-annual recaptures were not necessarily two year olds because from 2004 to 2007 all individuals received the same year-mark and these individuals may have been marked initially as metamorphs. To further examine whether adults return to breed in a subsequent year, we marked only adults in 2008 (N = 125). None of these were recaptured in 2009 (Table 1). Within-season recapture rates were especially high in 2008, which we attribute to a larger number of sampling sessions that were more closely spaced in time. Thus, based on our six years of mark-recapture data, we found no convincing evidence of any individuals that survived to be more than one year old.

Our data on body size patterns are consistent with these conclusions. Blanchard's Cricket frogs showed a significant difference in SVL among sampled months (Kruskal-Wallis Test: $\chi^2 = 541.0$, df = 5, $P < 0.001$). Post hoc tests revealed that body size did not differ significantly between May and June but that all other months were significantly different from one another (Fig. 1). In May and June of all years, captured individuals were always adult-sized and in breeding condition. But by July, we were unable to find any adult-sized individuals (other than the three adults found in July 2008). Individuals captured in July and August were exclusively metamorphs and juveniles (the mean SVL dropped from 24.8 mm in June to 15.0 mm in July; Fig 1) indicating a shift from a strictly adult-based age structure to one dominated almost entirely by juveniles (i.e., complete population turnover—no overlapping generations). This result cannot be explained simply as adult emigration from ponds after breeding since no frogs were ever found in other habitats and we have no evidence that any individuals returned to breed in any subsequent year. Subadults were only found in August, September and October but never in May, June or July. Some individuals from September and October were beginning to approach full adult body size (Fig. 1). Note that in Figure 1 individuals captured in October are smaller on average than those captured in September. This is an artifact of pooling data among years (2 samples were available from September (2006 and 2007) but only one from October (2004)). Breeding adult Blanchard's cricket frogs showed a significant sexual dimorphism in body size ($t = 6.686$, d.f. = 89, $P < 0.001$), with females being 10.2% larger on average than males (male mean 23.7 ± 1.7 SD, female mean 26.4 ± 1.9 SD).

While these data and that from other studies (see citations above), have suggested that Blanchard's Cricket Frogs are short-lived, other evidence suggests that this is not always the case. For example, using mark-recapture methods Gray (1983) found a few cricket frogs that had survived two winters. Using skeletochronological methods McCallum et al. (2011) documented a two-year old individual from Texas, and unpublished skeletochronological data from central Indiana has documented three-year old individuals (S. Perrill, pers. comm.). Zippell and Tabaka (2008) reported Blanchard's Cricket Frogs surviving nearly four years in captivity (using individuals collected from the same study site as we report on here). Thus, from these studies it seems clear that Blanchard's Cricket Frogs are physiologically capable of surviving longer than a single year and yet our study and others (Burkett 1984; Gray 1983) indicate that this rarely occurs under natural conditions.

So, why is survivorship so low? At our study site, it was not obvious that any likely predators were particularly abundant and indeed, we never witnessed any predation events. It is possible that infection with *Bd* is directly or indirectly involved in the short lifespan and low survivorship observed in our study. However, this also seems unlikely to us for several reasons. First, previous studies on Blanchard's cricket frogs have reported similar results to ours (see above) and some of these studies were probably conducted before any *Bd* was present (although this is impossible to ascertain for certain). Secondly, while Steiner and Lehtinen (2008) reported the St. Marys population to be positive for *Bd*, the infection rate was only 14% (based on PCR amplification of skin swabs from 42 individuals in 2006) and in six years of work at this site, we never observed any dead or dying frogs. Thirdly, if the frogs collected by Zippel and Tabaka (2008) were infected with *Bd* when collected (which seems likely), they survived a remarkably long time with the infection. Lastly, while catch-per-unit-effort is a rather crude measure of abundance, a linear regression analysis showed no significant linear trend in catch-per-unit-effort versus year ($F = 0.013$, $P = 0.914$, $r^2 = 0.03$). Thus, we found no evidence of decline in overall numbers during the study period and the nature of the high mortality rates remains unexplained.

Like other previous studies, our data suggest that newly recruited individuals grow rapidly and can be near adult size by the time the activity season ends (Fig. 1). In this population, most individuals metamorphose in July or August and breeding begins the following May. Therefore, sexual maturity appears to be attained in 9–10 months after metamorphosis (and an appreciable proportion of this time is spent over-wintering; Irwin et al. 1999). Compared to many other temperate hylids, this is an extremely rapid attainment of sexual maturity. For example, Lykens and Forester (1987) showed that male and female *Pseudacris crucifer* breed for the first time in their third spring (as two-year olds) and can live up to five years. Freidl and Klump (1997) found *Hyla arborea* to reach reproductive maturity in two years with a maximum documented longevity of six years. Two chorus frog species (*Pseudacris nigrita* and *P. ornata*) from the southeastern US reach reproductive maturity at a similarly rapid pace to that documented here (Caldwell 1987). However, some individuals were found to survive to breed more than once (maximum annual survivorship at her study sites was 33% and 11% for *P. ornata* and *P. nigrita*, respectively). Our mark-recapture and body size data suggest that Blanchard's Cricket Frogs grow to reproductive maturity in less than one year and that the first reproductive attempt is likely the last. However, as other studies have found older individuals and captive individuals are known to live nearly four years, this seems like less of an evolved life history strategy (i.e., semelparity) and more of a situation where extremely high extrinsic mortality is present.

This "facultative annual" life history of Blanchard's Cricket Frogs may be a factor in its decline in the northern part of its range. More long-lived species can potentially put off reproduction in bad years but given the short life span, this may not often be possible in Blanchard's Cricket Frogs. While a variety of factors have been implicated in the decline (see Gray et al. 2005 and Lehtinen and Skinner 2006 for summaries), a demographic structure such as the one confirmed here would seem to predispose this species to rapid population dynamics and frequent turnover events. To separate natural population fluctuations and local extinctions from human impacts, monitoring efforts for this species would likely benefit from a adopting a monitoring strategy on a large spatial and temporal scale.

Acknowledgments.—We gratefully thank the many people that help us catch frogs over the years including: S. Steiner, N. Busman, A. Skinner, B. Sheafor, D. Schook, K. Fry, N. Lara-Hayward, A. Novick, G. Carfagno, and E. Wojtowicz. We also thank the staff of the St. Marys Fish Hatchery for their interest in and support of our work. The methods used in this study were approved by the College of Wooster IACUC. Permits were issued by the Division of Wildlife at the Ohio Department of Natural Resources. We thank Michael Benard of Case Western Reserve University and two anonymous reviewers for comments that improved this manuscript. We gratefully acknowledge the College of Wooster, a US Fish and Wildlife Service State Wildlife Grant and the Henry Luce Foundation for funding.

Colonization of Hawaii Island by the Brown Anole (*Anolis sagrei*)

The Brown Anole (*Anolis sagrei* Dumeril and Bibron 1837) is a potent invasive lizard species. Native to Cuba and the islands of the Bahamas, it has been introduced to Florida, Hawaii, Taiwan, Jamaica, and Granada (Williams 1969; Campbell 1996; reviewed by Campbell, 2003). Florida introductions are the product of multiple colonization from across the native range of *A. sagrei* (Kolbe et al. 2004), and these highly admixed populations have further spread across the southeastern US displacing the native Green Anole, *A. carolinensis* (Voigt 1832) (Lee 1985; Tokarz and Beck 1987; Gerber and Echternact 2000; Campbell, 2003). In addition, molecular evidence indicates that Florida populations are the probable source of geographically widespread introductions to St. Vincent (Eales and Thorpe 2010), Hawaii, Grand Cayman, Taiwan, and Granada (Kolbe et al. 2004).

On the Hawaiian archipelago, *Anolis sagrei* was first reported from Oahu in 1992 and subsequently from Kauai and Maui (Kishinami and Kishinami 1996; Kraus 2003; 2006). McKeown (1996) observed this species in 1980 in a small residential neighborhood in Lanikai on windward Oahu, and further noted that, at that time, it had spread to adjacent towns and to the leeward side into Waikiki. Kraus (2002) reported establishment of additional satellite populations that included Pearl Harbor. He also noted that, where present, *A. sagrei* achieves high-density populations.

We report here that *Anolis sagrei* has new established populations on Hawaii Island. WJM first observed and collected *A. sagrei* on 29 May 2010 in irrigated ornamental vegetation on the grounds of a beach-front resort at Kahuwai Bay, a site (GPS 19.82828°N, 155.99130°W, WGS84, elev. 3 m) on the northwest coast of Hawaii Island approximately midway between Kona and Kawaihae. On 20 July 2010, we conducted a two-observer walking survey on the paths of this resort and an adjacent resort to the north (GPS 19.83006°N, 155.98877°W, WGS84, elev. 2 m). We conducted our survey during mid-day conditions with clear skies and light wind. We surveyed the more southerly resort between 1005 and 1150 h (105 min of continuous observation by two individuals), and observed 26 *A. sagrei*, 2 *A. carolinensis*, 4 Gold Dust Day Geckos (*Phelsuma laticauda*), and 1 Snake-eyed Skink (*Cryptoblepharus poecilopleurus*). We observed both juvenile and adult *A. sagrei* indicating that an established breeding population existed at the site. This resort is characterized by an open canopy with heavily irrigated, low ornamental shrubs and forbs along paved walkways, and scattered trees among the resort residences. At the adjacent resort to the north between 0935–1000 and 1340–1450 h (95 min total survey time), we observed 0 *A. sagrei*, 4 *A. carolinensis*, 6 *P. laticauda*, and 20 *C. poecilopleurus*. Although there was no apparent physical barrier to inhibit lizard movement between the two resorts (the two properties share a boundary), the northerly site is a cultivated xeriscape with a canopy of kaiwe (*Prosopis pallida*, a kind of mesquite), ironwood (*Casuarina glauca*), and ornamental palm trees with an open understory of scattered shrubs such as oleander (*Nerium oleander*).

Further to the south, a third resort at Kukio Bay offers irrigated habitat similar to the *Anolis sagrei*-inhabited resort, but is separated by an extension of a golf course that narrows to 50 m at the coast and expands inland. A second walking survey by one of us (WJM) on 2 December 2010 indicated that *A. sagrei* have not yet crossed this exposed, open grass barrier. Walks on three paths from the beach into the Kukio Bay resort (GPS 19.82127°N, 155.99661°W, WGS84, elev. 3 m) from 1053–1134 h (25 min observation time by one individual) in heavily irrigated habitat revealed 2 *P. laticauda* and 4 *C. poecilopleurus*, but no *A. sagrei*. Between 1150 and 1245 h, two segments of walking survey at the irrigated Kahuwai Bay resort (total 29 min observation time) yielded 4 *A. sagrei*, 1 *A. carolinensis*, 1 *Phelsuma laticauda*, and 1 *C. poecilopleurus*, while a 21-min survey of the northern xeriscaped resort between 1134–1150 h yielded 1 *A. carolinensis*, 1 *P. laticauda*, and 6 *C. poecilopleurus*. The three resorts at Kukio and Kahuwai Bay are collectively isolated from other suitable habitat for these *Anolis* lizards by extensive lava flows. These uncultivated lava flows are relatively young (1500–5000 yr B.P, based on USGS Misc. Investigations Series Map 1-2524-A), barren of trees and large shrubs, and receive less than 50 mm of annual rainfall (Juvik and Juvik 1998). We presume that *A. sagrei* cannot cross them without human assistance.

Another Hawaii Island colonization of *Anolis sagrei* has recently been reported from an eastern Hawaii Island residential neighborhood (19.68342°N, 155.08233°W, WGS84, elev. 102 m) in Hilo (Krysko and Granatosky 2010). On 27 January 2011, WJM surveyed this site and found that this species was distributed among a network of six residential streets south and west of the point of observation by Krysko and Granatosky (2010). The survey yielded 62 adult and juvenile *A. sagrei* and 2 Metallic Skinks (*Lamprophollis delicata*) over 47 min of walking where *A. sagrei* were present. The survey extended about 200 m beyond the last *A. sagrei* observation on any street direction away from the population center. GPS locations at the seven terminal points of *A. sagrei* observations yielded a circumscribed population with a minimum polygon area of 10.3 ha centered at 19.68218°N, 155.08287°W. No *A. carolinensis* were observed during the survey, although they are not uncommon in Hilo, and a resident confirmed that the newly introduced *A. sagrei* look different from the less abundant *A. carolinensis* typically seen among yard foliage.

Acting on the hypothesis that plant nurseries with inter-island wholesale plant outsourcing could be a pathway for anoles colonizing Hawaii Island, we visited two large retail nurseries in Hilo. *Anolis sagrei* was present in ornamental vegetation just outside one of these at the intersection of Railroad Avenue and

Makaala Streets (19.69844°N, 155.05820°W, WGS84, elev. 27 m). Voucher specimens of the three separate populations of *A. sagrei* have been deposited with the Bishop Museum in Honolulu: BMNH 36981–36984.

The populations of *Anolis sagrei* on Hawaii Island are likely very recent colonists, presumably from established populations on other islands in the state. While *A. sagrei* may have arrived at Kahuwai Bay and Hilo in imported ornamental plants, they pose an immediate threat of future, human-mediated expansion. The presence of both young and adult lizards at both sites confirms that these are already established breeding populations, and the species is clearly proficient at such stratified diffusion expansion as documented by Campbell (1996) for *A. sagrei* spreading through Florida to Georgia, Louisiana, and Texas. If its populations expand on Hawaii Island, we might expect *A. sagrei* to partially or completely displace *A. carolinensis*, as it has in Florida. As *A. sagrei* achieves remarkably high density populations where present on Oahu (Kraus 2002) and in our lizard counts on Hawaii Island, the species, alone or in combination with other invasive lizards, might pose a more significant threat to native arthropod species than *A. carolinensis* has in the past. Given the current limited distribution of *A. sagrei* on Hawaii Island, we strongly recommend that immediate action be taken to eradicate it before it can spread further.

Acknowledgments.—This work was supported by grant 57585 from the Hawaii Invasive Species Council, State of Hawaii to WJM and the NSF (DEB 0817042) and the UC Davis Agricultural Experiment Station to HBS. We thank Lisa Canale and John Coney for assistance with GPS databases and Kenneth L. Krysko for review of the manuscript. Procedures were approved by the University of Hawaii Institutional Animal Care and Use Committee.

The Harvest of *Antaresia maculosa* (Pythonidae) from West Papua, Indonesia

New Guinea is the largest tropical island in the world. It hosts 5–7% of the world's biodiversity (Dinerstein and Wikramanayake 1993; Myers et al. 2000) and 5% of the world's reptile species (Allison 2007). The island is politically divided between Indonesia and Papua New Guinea (PNG). The Indonesian provinces of West Papua (in the west) and Papua (in the east bordering PNG) were virtually closed to research through the latter part of the 21st century. As such, there are nearly 30% fewer reptile species recorded from Indonesian Papua compared to neighboring PNG (excluding islands in the Bismarck and Solomon Archipelagos), a difference likely explained by biases in search effort between the two countries (Allison 2007).

One family of large enigmatic snakes, the Pythonidae, has, however, been well documented. Australasia is home to the greatest diversity of python species in the world, with 12 species being known from mainland New Guinea (O'Shea 1996; Schleip 2008). Pythons are large bodied, non-venomous constrictors and are often brightly or contrastingly colored. As a result, they have been heavily exploited for the international pet trade, with large numbers of individuals being taken from West Papua each year to meet ever-growing domestic and international demand (Yuwono 1998).

Despite the relative conspicuousness of these snakes compared to other reptile species it was not until the year 2000 that O'Shea et al. (2004) discovered the genus *Antaresia* near the

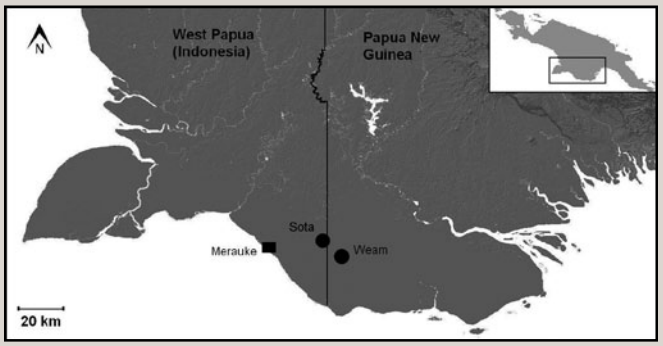

FIG. 1. Locality records of *Antaresia maculosa* in southern New Guinea (●) and the nearby port town of Merauke (■).

FIG. 2. An *Antaresia maculosa* from the vicinity of Sota, Papua, Indonesia.

village of Weam in southern PNG (Fig. 1). *Antaresia* is a genus of small, widespread python species common in many habitats in neighboring Australia (Wilson and Swan 2008). O'Shea et al. (2004) tentatively identified the species as *A. maculosa* (Spotted Python). Wuster et al. (2003) suggested that woodland species may have utilized two routes of migration between New Guinea and Australia (one from Queensland and another from the Northern Territory). *Antaresia maculosa* and *A. childreni* inhabit each area, respectively. Thus, further work is needed to validate the relationship of New Guinea specimens to those in Australia.

It is not currently known whether the lack of specimens collected in New Guinea is due to limited distribution, small population size, or merely limited collection effort in suitable habitat. Herein we report the first records of *Antaresia maculosa* from West Papua and discuss the implications of trade for the conservation of this python in New Guinea.

Observations.—While in the field between December 2010 and March 2011 we recorded four *Antaresia maculosa* individuals from the south of Papua (Fig. 2). These were collected by local people at three separate locations within a 5 km radius of the village of Sota (8.4280°S, 140.9916°E; WGS84) near the Indonesian/PNG border (Fig. 1). All pythons were found opportunistically; two were found at night while crossing a road. The snakes were collected by villagers and sold to two reptile traders in the nearby port town of Merauke. From Merauke, traders shipped the pythons to reptile dealers in the Indonesian capital, Jakarta, and we were told that they were destined for the international pet trade.

Discussion.—This is the first record of *Antaresia maculosa* from Papua. However, it is not surprising that the species occurs in the vicinity of Sota due to the habitat similarity with Weam in PNG (DJDN and JAL, pers. obs.). There are significant areas of suitable tropical woodland habitat in southern New Guinea (Bowe et al. 2007), so it is probable that the distribution of *A. maculosa* is considerably greater than the few records suggest.

Allison (2006) identified the conservation status of *Antaresia maculosa* from New Guinea as being of concern due to its restricted distribution and potential for exploitation by the pet trade. Of concern is that the genus was not previously known to occur in Papua, but has apparently been traded for at least the last five years. All Indonesian pythons are currently listed under Appendix II of the Convention on International Trade in Endangered Species of Wild Flora and Fauna (CITES), which regulates their export. In Indonesia the CITES management authority (PHKA) sets harvest quotas for Appendix II listed species with guidance from the Indonesian Institute of Science (LIPI). Species that are not assigned a quota cannot be harvested and because *A. maculosa* has not previously been recorded in Indonesia it does not have a harvest quota so cannot be legally traded. Traders indicated that the snakes were highly sought after for the international pet trade fetching up to US $80 each in Jakarta. It is not currently known whether they were, in fact, exported from Indonesia; however, given that the Indonesian domestic demand for reptiles is in its infancy this is highly likely. Because *A. maculosa* is currently unknown to the Indonesian CITES Management Authority any export from Indonesia is illegal.

The international trade in exotic pets is a growing threat to the world's biodiversity (Nijman 2010). Large numbers of reptiles from Indonesian Papua are harvested annually (DJDN and JAL, pers. obs), however, the effects of this trade have not been determined. At present, the status of *A. maculosa* in Papua is unknown. Now that the species has been confirmed as occurring in the region, surveys are needed to establish the sustainability of the trade in these pythons. We suggest that until the non-detriment findings required under Article IV of CITES for Appendix II species has been undertaken, no quota be set for the wild harvest and trade of these snakes.

Acknowledgments.—We thank Gunther Köhler and two anonymous reviewers for comments on an earlier draft of this manuscript.

Putative Predation and Scavenging of Two Sea Turtle Species by the American Alligator, *Alligator mississippiensis*, in Coastal Southeastern United States

The food habits of the American Alligator (*Alligator mississippiensis*) are well documented in many freshwater systems (salinity < 5 ppt) throughout its native range (Barr 1997; Delany and Abercrombie 1986; Gabrey 2010; Rice 2004). In marine (salinity > 25 ppt) and estuarine (variable salinity between 5 ppt and 25 ppt) habitats, however, the dietary interactions and food habits of *A. mississippiensis* have received little attention by researchers; limited data exist from Louisiana (Gabrey 2010; McNease and Joanen 1977; Wheatley 2010), Wassaw Island, Georgia (Tamarack 1988, 1993), and Cumberland Island, Georgia (Shoop and Ruckdeschel 1990). To date, no comparative analysis among marine or estuarine populations has been performed. The aforementioned studies indicate that *A. mississippiensis* foraging in marine and estuarine environments consume a variety of prey items including crustaceans (e.g., blue crab, shrimp, crayfish), horseshoe crab, teleost fishes (e.g., mullet, gar, shad, top-minnows), small mammals (e.g., nutria, raccoon, mink), and multiple species of wading birds. Here we report the first accounts of *A. mississippiensis* consuming marine reptiles: Green Sea Turtle (*Chelonia mydas*) and Loggerhead Sea Turtle (*Caretta caretta*).

Observations.—The most recent incident occurred on 25 September 2010 when a sea turtle flipper tag (# TTF-850) was recovered from the stomach of harvested adult male *A. mississippiensis* (total length [TL] = 352 cm, mass = 243 kg). This *A. mississippiensis* was harvested near the mouth of the New River, South Carolina, USA (32.100139°N, 81.088088°W), during a recreational hunt. The flipper tag was subsequently mailed to the Archie Carr Center for Sea Turtle Research (ACCSTR) to report the finding and to collect a returned tag reward.

During a sea turtle nesting survey along South Ponte Vedra Beach, Florida, USA on 17 September 2010 the carapace of a juvenile *Chelonia mydas* (straight carapace length [SCL] = 20.5 cm, straight carapace width [SCW] = 17.3 cm) was found in the sand along the surf (30.07329°N, 81.334190°W, Guana Tolomato Matanzas National Estuarine Research Reserve [GTM-NERR] catalog # 978). No plastron accompanied the carapace.

Eight conical puncture wounds were located laterally along the posterior of the carapace (Fig. 1). The puncture pattern was determined to be bite marks from an adult *A. mississippiensis* (K. Vliet and P. Gignac, pers. comm.). Verification was made chiefly due to the spacing between puncture wounds and the diamond-shaped indentations left when teeth did not fully perforate the bone, typical of crocodilian dentition (P. Gignac, pers. comm.). Given the size and spacing of the puncture wounds in the *C. mydas* carapace, we estimate that the *A. mississippiensis* involved was approximately 2 m TL. Additionally, markings on the turtle carapace indicate that the *A. mississippiensis* adjusted and manipulated the prey item in its mouth in an attempt to break up and swallow the *C. mydas* (Fig. 1).

Four observations of dead *C. caretta* being scavenged by *A. mississippiensis* were made on three separate Georgia barrier islands during ongoing sea turtle nesting surveys sponsored by the Georgia Department of Natural Resources (GADNR) and the U.S. Fish and Wildlife Service (USFWS). The most recent of these observations occurred at 2011 h on 10 May 1999. Caretta Research Project (CRP) personnel found the remains of a moderately decomposed sub-adult *C. caretta* (SCL = 55.0 cm, SCW = 45.9 cm, straight plastron length = 32.3 cm, straight plastron width = 37.9 cm, GADNR biopsy specimen # GA99051001-WASI) on the north end of Wassaw Island, Georgia (31.90395°N, 80.93882°W). CRP personnel pulled the carcass further up the beach toward the dunes so that it would not wash out later that night during high tide. Later that night, at 2300 h, the same personnel encountered a large *A. mississippiensis* (TL 2.7–3.0 m) investigating the aforementioned turtle carcass. The patrol left the *A. mississippiensis* and *C. caretta* carcass at 2330 h. The following day at 1200 h, CRP personnel traveled back the location of the carcass to take photographs of the specimen for GADNR documentation. Upon arrival, they found tracks from an adult *A. mississippiensis* originating at the stranding site and leading westward toward the dunes. The only remaining evidence of the turtle carcass at the stranding site was a depression where the turtle had been placed, two costal scutes, and the right front flipper. Pieces of the decomposing turtle were present along the alligator's route, which was

indicated by tracks leading into the dunes. The parts included three scutes (with epibiota still attached), five ribs, two hyoplastra, the upper and lower tomia, marginal, and pygal bones, horse-shoe crab claws (presumably stomach contents from the turtle), and portions of the esophagus with visible papillae. Turtle parts and alligator tracks led directly to an alligator hole located on the eastern edge of Beach Pond (31.90500°N, 80.94000°W) approximately 150 m away from where the stranded carcass had originally been placed.

Researchers on other Georgia barrier islands have observed three similar instances of sea turtle scavenging. An *A. mississippiensis* was seen scavenging a *C. caretta* carcass on Blackbeard Island (31.46732°N, 81.21866°W) in 1998 (D. Keineth, pers. comm.). Additionally, two instances occurred on Little St. Simons Island (31.26932°N, 81.30078°W) in 1995 and 1996, in which *A. mississippiensis* were observed carrying decomposing *C. caretta* carcasses down the beach to freshwater wetlands located behind the dunes (M. Robinson, pers. comm.).

Discussion.—Two other crocodilian species have been reported to consume sea turtles. *Crocodylus porosus* (Estuarine Crocodile) on Crab Island, Queensland, have been observed patrolling beaches to capture nesting *Natator depressus* (Flatback Sea Turtle) and *Lepidochelys olivacea* (Olive Ridley Sea Turtle) as female turtles search for suitable locations to dig nests and oviposit (Limpus et al. 1983; Sutherland and Sutherland 2003). It was estimated that during sea turtle nesting season *C. porosus* will consume a minimum of one adult turtle per week in this location (Sutherland and Sutherland 2003). Additional records of *N. depressus* predation by *C. porosus* are reported from Papua New Guinea (Hirth et al. 1993). In Costa Rica, *Crocodylus acutus* (American Crocodile) were recorded consuming nine adult *L. olivacea* (Ortiz et al. 1997) following nesting events.

In freshwater systems, *A. mississippiensis* have been documented to prey upon several freshwater turtle species within the genera *Apalone*, *Deirochelys*, *Kinosternon*, *Pseudemys*, *Sternotherus*, and *Trachemys* (Barr 1997; Delany and Abercrombie 1986; Gabrey 2010; McNease and Joanen 1977; Wolfe et al. 1987). In three Florida lakes, Delany and Abercrombie (1986) found turtles to be the most common prey type recovered from the stomachs of adult male alligators greater than 3.0 m total length. With regard to the information reported here, only two of the six observations potentially represent predation of marine turtles; the other four most certainly represent scavenging of dead turtle carcasses by *A. mississippiensis*.

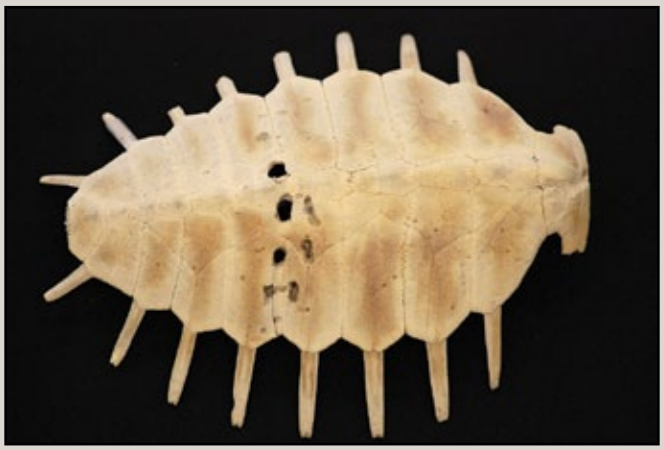

FIG. 1. Photograph of the carapace of a *Chelonia mydas* with bite marks identified as those of an *Alligator mississippiensis* measuring ca. 2 m TL.

Following the discovery of a flipper tag in the stomach of an adult *A. mississippiensis* on 25 September 2010, ACCSTR personnel found the tag had originally been applied to the right front flipper of a *Caretta caretta* that had been reared in captivity by the National Marine Fisheries Service Lab in Galveston, Texas, during 2005–2006. The turtle was used in the testing of turtle excluder devices and subsequently released off Sebastian Inlet State Park in Brevard County, Florida, on 6 July 2006. The last measurements taken in 2006 (SCL = 43.4 cm, SCW = 35.5 cm, mass = 10.63 kg) indicate that the turtle may have been >70 cm SCL in 2010 (P. Eliazar, ACCSTR, pers. comm.). At this size the *C. caretta* would have been far too large for an adult *A. mississippiensis* to consume whole (Erickson et al. 2003). Therefore, three plausible explanations exist for the presence of the flipper tag in the stomach of the harvested *A. mississippiensis*: 1) the alligator consumed the right flipper of the live turtle; 2) the alligator scavenged portions of the turtle after it had died; or 3) the alligator consumed the flipper tag after it had already fallen off the turtle. The type of flipper tag attached to this particular turtle (i.e., inconel metal) can remain attached for up to 5 or more years (P. Eliazar, pers. comm.) and it is highly resistant to corrosion. Thus, it is most likely that the flipper was removed from a live or stranded turtle and that the appendage was digested by the *A. mississippiensis*, leaving only the indigestible tag behind.

The second observation of potential predation was the finding of a *C. mydas* carapace on 17 September 2010. At the estimated size of 2 m TL, the alligator responsible for the bite wounds could not have swallowed the turtle whole. It is possible that the *A. mississippiensis* consumed the plastron, viscera, head, and appendages and then abandoned the remainder of the carcass, as these portions were missing from the turtle. We were unable to determine if the *C. mydas* was captured alive and killed by the *A. mississippiensis* or if the turtle was found stranded dead.

We speculate that one of two scenarios accounts for the *C. mydas* carapace on the beach. More probable, an adult *A. mississippiensis* crossed the 100–250 m of beach scrub habitat and FL-A1A from Guana Lake within the Guana Wildlife Management Area (GWMA) to access the beach shoreline. Guana Lake, a 10 mile long man-made impoundment (30.074216°N, 81.337261°W), is home to a large resident *A. mississippiensis* population as indicated from ongoing mark-recapture and GPS telemetry studies (J. Nifong, unpubl. data). Although rarely reported, *A. mississippiensis* have been observed on multiple occasions traversing FL-A1A and roaming in the surf along South Ponte Vedra Beach (J. Ellenberger, pers. comm.). Alternatively, the predation event could have taken place within the Intracoastal Waterway and the turtle remains subsequently carried out to sea through the nearby St. Augustine Inlet.

For sea turtle species that return to nesting beaches along the southeastern coast of the United States, peak nesting occurs in summer from June–August (S. Eastman, pers. comm.). Many of these nesting beaches are located within the home ranges of *A. mississippiensis* which occupy dune swales and coastal freshwater wetlands. *Alligator mississippiensis* using these coastal habitats regularly travel to estuarine and marine habitats in search of prey (Tamarack 1988), some spending as much as 87% of their time in fully marine waters as determined from GPS telemetry studies (J. Nifong, unpubl. data). During nesting season it is likely that *A. mississippiensis* encounter adult sea turtles along nesting beaches in shallow water or on-shore, providing the opportunity

for capture. In deeper open water, adult sea turtles would most likely evade capture by *A. mississippiensis*. Furthermore, a number of estuaries along this coast serve as nursery grounds for juvenile sea turtles such as *C. mydas* (S. Eastman, pers. comm.). Given that *A. mississippiensis* use the same habitat for foraging, it is possible that *A. mississippiensis* encounter juvenile sea turtles in these nursery areas while in search of prey. Although the observations reported here are widely separated both geographically and temporally (i.e., 15 years) we believe the predation of sea turtles by *A. mississippiensis* may occur regularly yet remain undetected in most cases.

Sea turtle strandings are often used to estimate the annual mortality of sea turtle species in the United States, even though two studies have questioned the practice (Shoop et al. 1998; Shoop et al. 1999). Because many factors influence the likelihood of a dead sea turtle washing ashore, the possibility exists that strandings represent only a fraction of the overall annual mortality actually occurring in near-shore waters. Additionally, because *A. mississippiensis* may removed a small percentage of beached turtles via scavenging, researchers are potentially underestimating the true number of dead turtles washing ashore, especially in coastal habitats supporting high alligator densities. More information is needed to determine the frequency of these scavenging events before we can accurately assess the effect of *A. mississippiensis* scavenging on the real number of dead turtles washing ashore annually along the southeastern Atlantic and Gulf coasts.

Acknowledgments.—We thank all those who contributed personal observations, personal communications, and identification verification: P. Eliazar, P. Gignac, K. Vliet, J. Ellenberger, D. Keineth, and M. Robinson. Additionally, we thank the Georgia Department of Natural Resources, United States Fish and Wildlife Service, and Guana Tolomato Matanzas National Estuarine Research Reserve for funding ongoing sea turtle nesting surveys, which provided the opportunity to make many of the observations reported here.

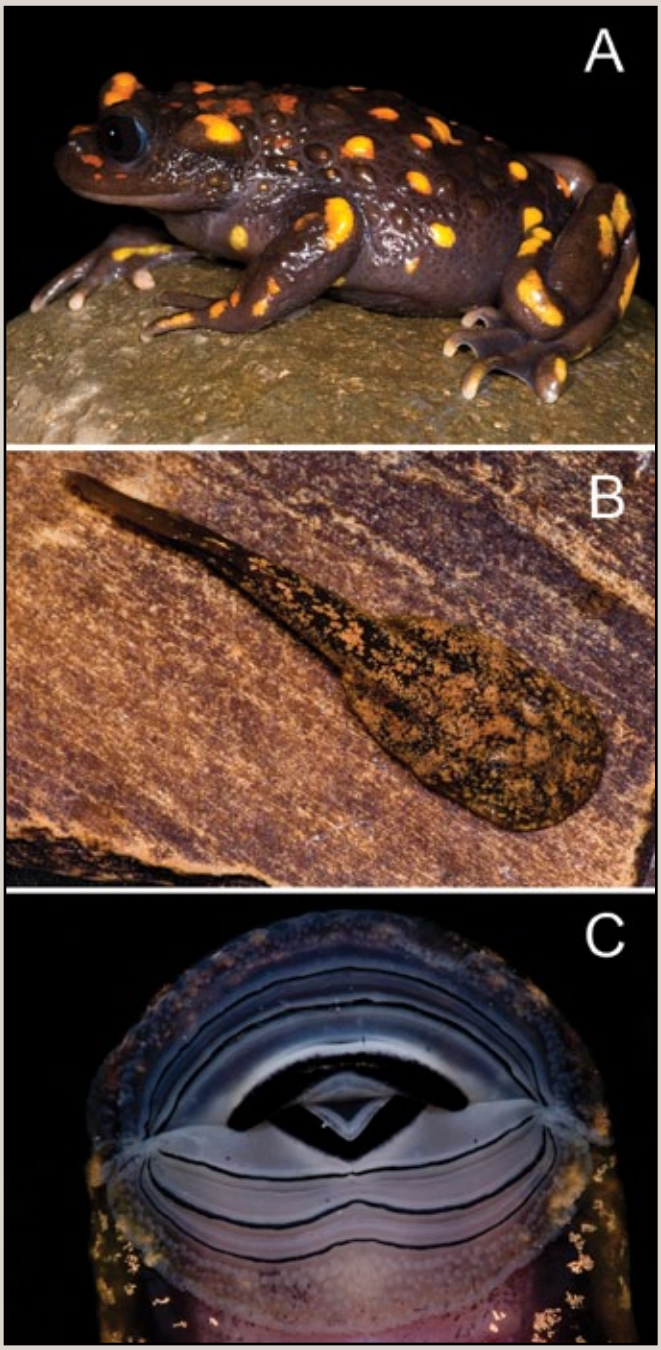
Sandwiched between the Andes Mountains to the east, the Pacific Ocean to the west, and the Atacama Desert to the north, a narrow strip of southern Chile houses temperate humid forest (Aravena et al. 2002). These forests are biologically unique owing to their isolation. The temperate humid forests of southwest South America have been isolated since the Tertiary Period (Aravena et al. 2002; Villagrán and Hinojosa 1997) and house significant numbers of endemic plants and animals (Aravena et al. 2002; Armesto et al. 1996; Arroyo et al. 1996). Not surprisingly, the amphibian fauna is largely endemic. There are minimally 37 anurans unique to these forests, constituting no less than 85% of the regional amphibian fauna including three endemic genera and an endemic family to Chile (*Calyptocephalella*, *Insuetophrynus*, *Telmatobufo*, and the Calyptocephalellidae, respectively) (Díaz-Páez et al. 2008; Vidal et al. 2008). One of the amphibians found only in these southern forests is the Chile Mountains False Toad, *Telmatobufo venustus* (Figs. 1A–C).

In 1899, Philippi described *Bufo venustus* from four specimens collected in the Andean foothills of southern Chile. In 1952, Schmidt erected the genus *Telmatobufo*. Formas and Veloso reassigned *Bufo venustus* to *Telmatobufo venustus* in 1982. The genus contains three other species: *T. australis* (Formas 1972), *T. bullocki* (Schmidt 1952), and *T. ignotus* (Cuevas 2010). All known *Telmatobufo* are endemic to southern Chile. Formas et al. (2001) discussed taxonomic relationships among the then-recognized three species of *Telmatobufo*. Hypothesized phylogenetic relationships between *Telmatobufo* and *Calyptocephalella* (=*Caudiverbera*) have been proposed (e.g., Correa et al. 2006; Formas and Espinoza 1975; Frost et al. 2006; Lynch 1978; Núñez et al. 2000). Correa et al. (2006) indicated that the closest living lineage of frogs to *Telmatobufo* and *Caudiverbera* (now *Calyptocephalella*) (tribe Calyptocephalellini) are Australian myobatrachids and limnodynastids. The Calyptocephalellini may be ancient. Núñez and Formas (2000) indicated that the lineage that led to the Calyptocephalellini diverged around 35 million years ago and that the extant species of *Telmatobufo* emerged approximately 20–25 million years ago. Donoso et al. (2010) suggested that the Calyptocephalellidae may represent a relict lineage of Gondwanian origin.

Telmatobufo venustus is known from the western slopes of the Chilean Andes from 28.5° to 38.5°S, and between 1500 and 1700 m elevation (Díaz et al. 1983; Stuart et al. 2008). There are three known historical areas where *T. venustus* has been reported: Cordillera de Chillán, Provincia de Ñuble (VIII Región), Ralco, Provincia del Bío-Bío (VIII Región), and Altos de Lircay, Provincia de Talca (VII Region) (Formas et al. 2001). We refer to "areas" rather than localities because in one of the three cases above, the exact locality is not known. The specific location of the type locality within the Cordillera de Chillán was not included in the description of the species, but is simply referred



to as the Andean foothills of southern Chile, east of Chillán and Cautín (Philippi 1899). No observation of the species has been reported from that area since. One tadpole was reported from Ralco Province and no further observations have been reported there (Díaz et al. 1983); further, the locality now lies beneath a lake created by a dam that went in after the tadpole was observed there. The only locality for which recent observations have been made by the authors here and in the literature is Altos de Lircay, Provincia de Talca (VII Region) (Fig. 2).

The Chile Mountains False Toad inhabits temperate *Nothofagus* (Southern Beech) forests (Stuart et al. 2008). It has been proposed that a stream-adapted tadpole is a shared character among all *Telmatobufo* (Cuevas and Cifuentes 2009; Formas et al. 2001). This has been observed in *T. venustus* (Díaz et al. 1983) and in *T. australis* and *T. bullocki* (pers. obs.). Veloso et al. (2004; see also Stuart et al. 2008) indicated that "reproduction is unknown, though it probably takes place by larval development in water." The statement is partly inaccurate as the tadpole of *T. venustus* had already been described by Díaz et al. (1983) as a stream-adapted "mountain type larvae" with an oral disk that serves as an anchor in fast flowing mountain streams (Figs. 1B, 1C).

Telmatobufo venustus is secretive and all species of *Telmatobufo* appear to be seldom encountered. Cuevas (2010) indicated that "Since the description of this genus (Schmidt 1952), specimens of only 20 adults of the three species have been collected. These have been from Cabrerias, Llancahue, Cerro Pûschel (*T. australis*); Parque Nacional Nahuelbuta, Rucapehuen (*T. bullocki*); and Altos de Vilches (*T. venustus*)." Adult *T. venustus* were recorded for the first time in 100 years in 1999 (Stuart et al. 2008; Veloso et al. 2004). The larval form was not described until 1983, 84 years after the species' description. Veloso (2006) reported that only adult specimens, not juveniles or subadults, have been observed. During our recent (2011) surveys we encountered several specimens of the even rarer *Telmatobufo bullocki* (Figs. 3, 4) in *Nothofagus* forests of the Butamalal River drainage system (Fenolio et al., in prep.).

Habitat loss, particularly conversion of *Nothofagus* forests to pine and eucalyptus, is affecting *Telmatobufo* (Cuevas 2010; Rabanal and Núñez 2009; Stuart et al. 2008; Veloso et al. 2004). Cuevas and Cifuentes (2009) argued that the life history of frogs like *Telmatobufo*, having a stream-adapted tadpole with specific habitat requirements, puts them at risk owing to anthropogenic environmental changes in south Chile. One example concerns heavy sediments and siltation of the streams from human activities in the areas where *Telmatobufo* are found; siltation could adversely affect the larval stages of these ancient amphibians (Sánchez 2010). Forest fire comprises another significant threat to *T. venustus* (Veloso 2006). More survey work is needed to determine population status (Stuart et al. 2008; Veloso et al. 2004).

We performed visual surveys of streams in the Reserva Nacional Altos de Lircay, in the Región del Libertador Bernardo O'Higgins, Chile, from January through April of 2010 and 2011, for *T. venustus*. Fifty person-hours were spent searching two streams within the park; due to concerns about illegal collecting, the exact locations are not included here. We encountered 10 adults, all at night along mountain streams, on boulders, and in spray zones (Figs. 2, 5–7). Skin swabs from eight of the ten specimens were sent to the lab of one of the authors (M.G.L.). No frogs were removed from the wild. The swabs tested negative for amphibian chytrid fungus (*Batrachochytrium dendrobatidis*, or *Bd*). Amphibian chytrid fungus is a concern as it was first reported in Chile by Solís et al. (2010) in an invasive amphibian (*Xenopus laevis*) and subsequently by Bourke et al. (2010, 2011) in native species.

FIG. 1. (A) An adult *Telmatobufo venustus* at rest on a streamside boulder; note the developed webbing between the toes. (B) *Telmatobufo* tadpoles are dorsoventrally flattened and have a suctorial disk (C) for attachment to the substrate in flowing waters.

Methods for detecting *Bd* were as follows: Frogs were collected and swabbed using a new set of vinyl gloves per specimen. Frogs were individually swabbed using sterile polyester tipped applicators (Puritan Medical, Guilford ME). Polyester tipped applicators were gently wiped on the gular region, the flank region, the bottoms of the hands and feet, and along the ventral surface for 12 passes per body region. When dry, the tips of the swabs were transferred to individual sterile tubes and stored at 4°C until

FIG. 4. Obstacles to finding *Telmatobufo bullocki* include difficult terrain and the frog's habit of burying itself deep under large logs. This adult female was found after hours of searching.

extracted and assayed. The tip of the polyester applicator was transferred to a 2 ml cryovial, 100 µl of Prepman Ultra (Applied Biosystems, Foster City, California) was added followed by 50 mg 0.5 mm glass beads for extraction. The tubes were vortexed and homogenized for 1 min in a Mini BeadBeate (Biospec Products), then placed in boiling water for 10 min, cooled for 1 min, centrifuged at 14,000 rpm for 3 min in a Marathon 16KM centrifuge (Fisher Scientific) after which the liquid was transferred using a micropipette to clean 0.6 ml microcentrifuge tubes. The recovered supernatant was then stored at 4ºC until assayed using the quantitative real-time PCR protocol of Boyle et al. (2004) using 1 µl of the extract as the DNA template.

The apparent absence of *Bd* in one remaining population of *T. venustus* may not be conclusive owing to the problem faced by all field biologists working with rare or reclusive species—small sample sizes. Invasive species have done irreparable damage to native Chilean fauna (De Buen 1959; Jaksic, 1998; Jaksic and Fuentes 1991; Jaksic et al., 2002; Lobos and Jaksic, 2004; Lobos and Measey, 2002; Lobos et al. 1999, 2005). Our field team has surveyed streams for three species of *Telmatobufo*. Where trout

are absent (one stream for *T. venustus*, one stream for *T. bullocki*, and one stream for *T. australis*), their tadpoles have been found. During the surveys in Reserva Nacional Altos de Lircay we have encountered adult *T. venustus* in two streams but found tadpoles in only one of them. Introduced salmonid fish (Rainbow Trout, *Oncorhynchus mykiss*) are common in the stream where we have been unable to locate tadpoles. A local park ranger and a former landowner indicated that trout were introduced to the first stream in the mid-1960s. Introduced trout could prey on the tadpoles, and in fact introduced fish have been implicated in other montane stream amphibian declines (e.g., Adams 1999; Collins and Storfer 2003; Kats and Ferrer 2003). If indeed successful recruitment has been dwindling, or has stopped altogether, we may have observed the last, aged individuals of a non-reproducing metapopulation at the first stream.

Based on these field surveys and an analysis of the literature, we make several recommendations for conservation measures with *Telmatobufo venustus*. This species is listed currently as EN, endangered (IUCN 2011) but it is now apparent that it meets two of the conditions for an elevated IUCN listing of CR, critically endangered (only one is required; IUCN 2011): 1) In category B, subcategory 1, of section V, this species has an estimated range of less than 100 km^2; Reserva Nacional Altos de Lircay is a small reserve of 12.163 hectares (= 0.12163 km^2) in size and encompasses the only known streams in the area where the species has been reported during the past 25 years. There are two subconditions: The first subcondition (category B, section 1, subsection a), is met in that if there are multiple remaining populations outside of Reserva Nacional Altos de Lircay, they are severely fragmented; however, we suspect that there is only a single location with viable populations of the species (Reserva Nacional Altos de Lircay). The second subcondition (category B, section 1, subsection b (iii)), is met in that the quality of larval habitat is degrading due to the presence of the introduced salmonid fish (Rainbow Trout, *O. mykiss*). Further habitat degradation may occur as a result of *Bd*, which has been reported in non-native *Xenopus* from Chile (Solís et al. 2010) and in native species from south Chile (Bourke et al. 2010, 2011).

2) Category A, subcategory 4, of section V, requires that a species have an observed, estimated, inferred, projected or suspected population size reduction of X ≥ 80% over any 10-year or three-generation period, whichever is longer (up to a maximum of 100 years in the future), where the time period must include both the past and the future, and where the reduction or its causes may not have ceased OR may not be understood OR may not be reversible, based on (category A, section 1, subsection e): the effects of introduced species (Rainbow Trout, *O. mykiss*, in many of their breeding streams) and the potential arrival of an emergent infectious amphibian disease (*Bd*), now present in south Chile.

Second, based on significant and continuing habitat loss and on subsequent population fragmentation that all *Telmatobufo* species have suffered, we propose that ex-situ assurance colonies of *Telmatobufo*, including *T. venustus*, be established immediately within Chile. The National Zoo of Chile in Santiago and the Atlanta Botanical Garden have a four-year-old partnership that developed facilities to support a captive assurance colony of Darwin's Frogs, *Rhinoderma darwinii*, at the zoo. That facility is now operational, amphibian keepers have been trained and are in place, and the program has reproducing groups of *R. darwinii*. These stakeholders are looking to expand their program to support other threatened amphibians of Chile. Facilities exist now and permits have been obtained from the government of Chile for the immediate creation of assurance colonies of three species of *Telmatobufo* (*T. venustus*, *T. bullocki*, and *T. australis*). The goal is to create the assurance colonies before wild populations drop to numbers so low that assurance colonies cannot be created. Amphibian specialists from the Atlanta Botanical Garden's amphibian conservation program, with experience in captive breeding of endangered amphibians, will support the effort at the National Zoo of Chile in the same way that the zoo was supported while the Darwin's Frog facility was created and populated with groups of frogs. Fund raising is a joint venture. Involved stakeholders believe that retaining the assurance colonies within Chile provides the effort with local enthusiasm for the conservation of native and endangered amphibians, rendering a project that is likely to endure. Ensuring the future survival of the ancient Calyptocephalellidae requires an expansion of existing partnerships to involve the zoological community, amphibian conservation oriented programs (such as those at the Atlanta Botanical Garden), the Chilean Forestry industry, and governmental wildlife authorities and respective agencies. Only with support from all pertinent parties can work toward a comprehensive conservation program occur. Such a program could be modeled after a collaborative effort like Partners for Amphibian and Reptile Conservation (PARC; see Gibbons 2005; http://www.parcplace.org/).

PHOTO BY WILLIAM W. LAMAR

FIG. 7. Specimens of *Telmatobufo venustus* have been located at night perched beneath enormous streamside boulders.

Third, the remaining streams in which *T. venustus* has been observed are all within the Reserva Nacional Altos de Lircay. It would be presumptuous and inappropriate to mandate anything here but we recommend that the reserve consider the implementation of a program to control the trout in the headwater tributaries of these streams. The first step would have to include removal of the introduced salmonid fishes from the stream where surviving individuals of *T. venustus* have been observed. After this, fish exclusion devices would have to be implemented along lower regions of the streams, below the areas where frogs can still be found, to prevent recolonization of the headwaters by trout. Because these streams are the only remaining localities in which *T. venustus* has been recently observed, it is critical to take action within the reserve to protect remaining populations. A collaboration between the organizers of assurance colonies of *T. venustus* and the Reserva Nacional Altos de Lircay would be an ideal next step in that tadpoles could be released, post fish removal, in appropriate drainage systems to help bolster existing lineages (keeping careful track of and releasing appropriate genetic stocks per stream according to parentage). An additional step toward the conservation of *T. venustus* in Reserva Nacional Altos de Lircay might be signage for visitors to the reserve, making them aware of these unique natural treasures that are endemic to Chile and in fact, may now only be found within the boundaries of the reserve. Special funds pertaining to the conservation of Chile's critically imperiled amphibians, from the Chilean government, would also go a long way toward these ends.

Finally, we recommend regular monitoring of wild populations for emergent infectious amphibian disease such as *Bd* and ranavirus. Since monitoring of these diseases in wild populations of Darwin's Frogs already occurs via the partnership between the National Zoo of Chile and the Atlanta Botanical Garden, an expansion of that program to include regular disease monitoring in all *Telmatobufo* species is in progress.

Acknowledgments.—We are grateful to M. Suyemoto for expert technical assistance with PCR analysis. We thank the following for funding assistance: the Association of Zoos and Aquariums and their Conservation Endowment Fund (grant No. 08-809), the Sophie Danforth Conservation Biology Fund, the Shared Earth Foundation, the George and Mary Rabb Foundation, and the Chicago Board of Trade Endangered Species Fund. We thank the two anonymous reviewers of the manuscript for comments and corrections. We also wish to acknowledge the support of SSAR's Thomas Beauvais Fund in making possible the publication of color figures.

Using Spot Pattern to Identify Individual Long-Tailed Salamanders

The use of simple and inexpensive amphibian monitoring techniques is often necessary due to limited time and funds. When individuals can be uniquely identified, mark-recapture can be used to estimate abundance, other demographic variables (e.g., survivorship and recruitment), habitat use and individual growth rates (Donnelly and Guyer 1994). In comparison with other marking techniques, spot pattern recognition is less invasive and generally costs less than other methods. However, it is only useful when markings are variable and the pattern does not change ontogenetically (Donnelly et al. 1994; Plăiaşu et al. 2005).

Spot pattern recognition has been used successfully in a variety of studies for individual identification of amphibians (Ferner 2007, 2009; Schlüpmann and Kupfer 2009), and has been recommended as an ideal method for salamander identification by Ferner (2007) (e.g., Loafman 1991; Plăiaşu et al. 2005; Tilley 1980). Varying spot pattern recognition methods exist, but most rely on overall pattern, spot count, or a combination thereof. In this study, we tested whether head-spot counts can be used as a component of overall spot pattern recognition in order to identify individual Long-tailed Salamanders (*Eurycea longicauda longicauda*) in the field. We also employed digital photographs of Long-tailed Salamanders to determine if the number of head-spots was related to salamander size.

Methods.—Long-tailed Salamanders are found under rocks and woody debris near forested springs or streams (Petranka 1998). In southeastern Pennsylvania and northern Delaware, they are commonly found in springhouses because these houses are damp and dark and ideal substitutes for their natural habitat. These salamanders are yellowish-orange to yellowish-brown with black spots (Petranka 1998), which makes these salamanders an ideal study organism.

We captured Long-tailed Salamanders from four populations associated with springhouses in southeastern Pennsylvania and northern Delaware. We visited springhouses every 12–16 days during 2002–2006 during peak activity periods (April–May and August–November), and every 19–23 days during the summer (June–July). We waited until after dusk to search outside springhouses because Long-tailed Salamanders forage at night (Petranka 1998). Using aquarium nets inside springhouses and by hand when outside, we captured individuals and them placed into 25 × 25 cm zip lock bags containing paper towel moistened with water from the springhouse.

We measured, weighed, and determined the sex of each salamander, noting whether the individual was gravid or had any injury or deformity. For measuring, we placed salamanders into a 15 × 15 cm zip lock bag so they could easily be straightened and turned upside down without injury. We recorded snout–vent length (SVL) and tail length (TL) to the nearest 1 mm, noting broken or regenerating tails, and weighed each salamander to the nearest 0.01 g using a digital balance. We determined sex by checking for secondary sexual characteristics: specifically, enlarged teeth and a submandibular mental gland in males and the presence of white developing ova that can be seen through the skin lateral to the belly on females. After we documented physical characteristics, we digitally photographed each salamander in the dorsal orientation (Donnelly and Guyer 1994).

To identify individual salamanders, we counted each dorsal spot from the tip of the nose to the beginning of the forelimbs, ignoring the lateral spot pattern down the sides of the body (Fig. 1). We considered a spot to be any mark (oval or otherwise) that had a distinct black coloring. If a spot was faint or blurry, we classified it as a spot if we could see a definite black mark in the center as opposed to being uniformly faint throughout. This criterion was only used for faint or very small markings. If the marking was faint throughout but still large enough to be definitively seen as a spot, then we counted it. When two spots touched, we classified it as a single spot if the outline created was a generally continuously oval with minimal indentation where the spots conjoined. We classified two spots as independent if the outline created allowed for the two spots to have a major indentation at the point of contact. We counted spots if more than half of the total area of a spot fell anterior to the forearms.

We sequentially organized digital photographs from capture events for each study site. We then used this database to visually match more than 4000 photographs of newly caught individuals from subsequent capture events. Because it was not logistically feasible to inspect more than 4000 photographs, we took a random sample of the photographs. After identification, we sorted captures into seven 0.5-cm size categories based on SVL (range

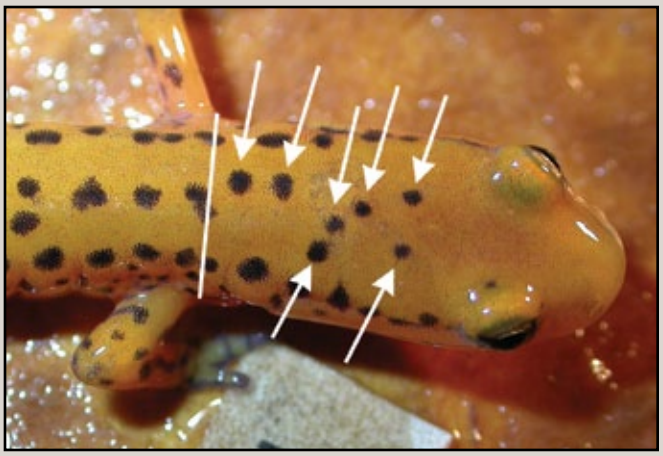

FIG. 1. Using digital photographs to determine spot number for an individual Long-tailed Salamander, we counted spots from the tip of the nose to the beginning of the forelimbs, ignoring the lateral lines running down the sides of the body. The solid line indicates where counting stopped.

3.5–6.9 cm). We established the seven categories by graphing the data to find natural breaks. For each study site, we randomly selected 40 individuals of each size group for a total of 926 individuals. We only selected unique individuals; recaptures were not included in the analysis. We used an ANOVA, blocked for site, to determine the relationship between spot number and size ($\alpha = 0.05$). When we detected differences, we used a planned Least Significant Differences mean separation test to determine differences among means (Sokal and Rohlf 1995). We did not use a linear regression because the relationship was curvilinear and the presentation of categories provided a clearer picture of the data as it related to our objectives.

Results.—Spot number increased with the size of salamander ($F_{6,925} = 20.87$, $p < 0.001$; range 13–21). The increase in number of spots was small (< 2) except for large salamanders (6.0–6.9 cm), which increased by 2.5–3 spots per size category. The number of spots was usually similar in adjacent size categories except for salamanders 6.0–6.4 cm and 6.5–6.9 cm, which were not similar to any other size categories (Table 1). Although spot number increased as a salamander grew, photographic analysis showed that the general pattern of spotting stayed the same. Identification of individual salamanders was possible because the addition or subtraction of a few spots did not deter recognition of the overall pattern (Fig. 2).

Discussion.—Head-spot counts varied by size groupings in *E. longicauda* suggesting that head-spot number changes over time; however, spot pattern recognition is still a useful technique. Approximately half (50.4%) of the salamanders caught were within groups 3, 4, or 5, which are the groups in which spot number remained similar. Therefore, half the captured salamanders had spot numbers that did not change among size groupings. When salamanders grew to 6.0–6.4 cm and 6.5–6.9 cm (groups 6 and 7, respectively), spot number increased. Because we did not determine the age of the salamanders, we cannot determine if spot addition is related to age or to size.

Despite an overall mean spot number increase, many potential points for identification existed so mismatches were unlikely to occur. Because we rarely observed spots disappearing and spots tended to appear rather than disappear, previous identification markers remained visible. As a result, the most important component to identification was overall pattern recognition despite the increase in mean spot number. These findings highlight the importance of understanding ontogenetic differences among salamander species before incorporating spot pattern recognition into a mark-recapture study. Our results challenge the assumption that pattern marks must stay constant in order for spot pattern recognition to be successful (Ferner 2009; Gill 1978) since changes in head-spot counts did not affect overall spot pattern recognition.

Many studies have successfully incorporated head-spot counts and spot pattern recognition techniques (Grant and Nanjappa 2006; Pliau et al. 2005; reviewed by Schlüpmann and Kupfer 2009). However, we recommend conducting a pilot study on head-spot counts to determine if data suggest spots remain constant through time for the species of interest. If head-spot counts do change, a pilot study could confirm that using overall

FIG. 2. Examples of three Long-tailed Salamanders that we recaptured after two years. Salamanders on top captured in 2004 (top) were recaptured again in 2006 (bottom). Note that addition or subtraction of a small number of spots does not deter recognition of overall pattern.

pattern recognition exclusively can still be a useful aid to individual identification.

Acknowledgments.—We are grateful to Barley Van Clief and the Pennsylvania Resource Council, Tri-State Bird Rescue and Research, Fred and Cindy von Czoernig, and Michael and Angie Riska for allowing us access to their property and springhouse. We especially thank Kevin Fryberger for coordinating site visits and Jim White for assistance with photography and field work. We also thank P. Adkins, L. Allison, G. Colligan, K. J. Cutting, S. T. Very Small, Light Dipole Harmonic Tags for Tracking Small Animals

Tracking animals provides a detailed picture of their behaviour and can be important in understanding their ecology. Tracking is especially useful for elucidating the ecology of animals that are cryptic during all or parts of their life cycle (Heyer et al. 1994; Langkilde and Alford 2002; Reynolds and Riley 2002). Amphibians, for example, can be hard to study outside breeding aggregations, and wildlife telemetry can provide insight on otherwise unknown aspects of their biology (Heyer et al. 1994; Naef-Daenzer 1993; Naef-Daenzer et al. 2005; Rowley and Alford 2007a, b, c; Rowley et al. 2007).

Tracking devices should be small and unobtrusive (Hamley and Falls 1975; Heyer et al. 1994; Korpimaki et al. 1996; Ormingston 1985). Many guidelines recommend that the mass of tracking devices should not exceed between 5% (Wilson and McMahon 2006) and 10% (Blomquist and Hunter 2007; Gursky 1998; Richards et al. 1994) of the animal's body mass, particularly when tracking vertebrates. Package shape is also an important consideration; devices must not impede the tracked animal's movement (Blomquist and Hunter 2007; Greenwood and Sargeant 1973; Wilson and McMahon 2006). Finally, devices should have long useful lifespans, reducing the frequency of capture, handling, and other potentially stressful procedures (Langkilde and Alford 2002; Pereira et al. 2009). Tracking devices, therefore, typically reflect compromises among the needs for small size, low mass, long life, and high durability.

Two main approaches can be taken to track animals using radio signals. Tracking using tags containing active radio transmitters allows researchers to locate subjects and identify them individually (Heyer et al. 1994; Indermaur et al. 2008; Naef-Daenzer 1993; Naef-Daenzer et al. 2005; Rowley and Alford 2007a, b, c), and may enable the retrieval of additional information, such as the subject's physiological status and local environmental conditions (Reynolds et al. 2002), but the method is restricted to larger species or individuals, due to the relatively high weight of the battery, harness, and transmitter package (Langkilde and Alford 2002; Naef-Daenzer 1993; Naef-Daenzer et al. 2005; Rowley and Alford 2007c). Currently, minimum body mass of animals tracked using radio-transmitters is 2–4 g, based on a minimum package plus harness mass of 0.2 g for the smallest available transmitters and limitations to 5–10% of the body mass (Naef-Daenzer et al. 2005). These extremely light tags have extremely short battery lives, measured in days; this further restricts their usefulness in field studies, where animals may require some time to return to normal behaviour following tag attachment (Langkilde and Alford 2002; Rowley and Alford 2007c).

It is also possible to use tags that do not contain their own power sources. These tags fall into two categories: PIT (Passive Integrated Transponder) tags and harmonic radar tags. PIT tags,

often used as implantable means of individual identification, eliminate the need for the battery by using an induction coil to provide the power to emit a very weak radio signal. However, the need for a powerful magnetic field and the very weak signal emitted limit their range and make them unsuitable for tracking applications (Ohashi et al. 2010; Vinatier et al. 2010). For tracking, the main alternative to self-powered transmitter tags is harmonic radar, also known as harmonic direction finding. The tracking devices used with this technology consist of a single diode with an attached antenna, weighing as little as 0.11 g (Pellet et al. 2006). They absorb radio waves emitted by a handheld transceiver, re-emitting some of the energy as radio signals at a harmonic frequency of the initial signal. The re-emitted signal is detected by the transceiver unit, using a directional antenna. Compared to typical radio transmitter tags, harmonic tags have some disadvantages. First, they do not emit individually identifiable signals, so individuals carrying tags have to be distinguished by means other than a signal ID (Rowley and Alford 2007c). Second, their maximum range is typically less than that of tags containing radio transmitters (Langkilde and Alford 2002; Rowley and Alford 2007c). Finally, harmonic direction finding is more difficult than radiotracking in environments in which radio signals are attenuated (i.e., dense vegetation may absorb signals), or in environments that naturally re-emit radio waves (i.e., some boulders and rocky outcrops; Rowley and Alford 2007c). The great advantages of harmonic direction finding are that (i) it allows tracking of vertebrates too small (typically approximately 2 g) for even the smallest available radiotransmitters, and (ii) tags are not limited by battery life, and so can be used as long as they remain attached to the subject (Rowley and Alford 2007c).

The small size of tags used in harmonic direction finding has allowed tracking of a variety of vertebrates (Pellet et al. 2006, Rowley and Alford 2007a, b, c; Rowley et al. 2007) and flying insects (Naef-Daenzer et al. 2005, O'Neal et al. 2004, Vinatier, 2010; Williams et al. 2004). Tags used with a harmonic direction finder are often constructed from Schottky diodes (Langkilde and Alford 2002; O'Neil et al. 2004; Rowley and Alford 2007c; Williams et al. 2004), which are commonly used in electronic circuits. Schottky diodes are semi-conductor diodes that lower the voltage in an electrical current, have a very low forward-voltage drop, and a fast switching action (hence their sensitivity to radio waves). In a harmonic direction finding tag, the diode receives a signal from a transceiver unit, such as the commercially available Recco™ transceiver, and re-emits a signal at a doubled frequency (Langkilde and Alford 2002; Rowley and Alford 2007c).

Many studies have used germanium Schottky diodes in standard cylindrical packages (Langkilde and Alford 2002; Rowley and Alford 2007c). Tags have typically consisted of one germanium diode with a single antenna soldered to the cathode (a monopole antenna). The diodes typically weigh approximately 0.2 g, and thus the minimum mass of an assembled tag is approximately 0.27 g, limiting the size of study animals to a minimum of 2.6–5 g depending on the particular rule for permissible package size that is followed (Blomquist and Hunter 2007; Gursky 1998; Richards et al. 1994; Rowley and Alford 2007c; Wilson and McMahon 2006).

We have developed a new design for harmonic tags that substantially reduces their size and mass while maximizing clarity and range of the signal. We use surface-mount diodes, which are smaller and lighter than germanium diodes but require a different tag assembly method (see Pellet 2008 for a technique using similar diodes). In contrast to Pellet and others (2008), we use a dipole antenna configuration that provides a strong signal using short, light antennae as well as a different attachment method (using a silicone belt integral to the package) allowing us to construct tags that weigh 0.13 g. These can be attached to animals weighing a minimum of 1.3–2.6 g. A previous study using monopole antennas (Rowley and Alford 2007c) found that detection distances were ca. 0.5 m when tagged animals were under rocks or in a few cm of water, and measured a maximum detection distance in the canopy of 12 m. Here our tags achieved ranges of more than 20 m when tested in open habitats, decreasing as antennae are trimmed further than the lengths described here. In addition to this, the anode antennae unique to our tag increases the range provided by submerged tags to 2–5 m depending on obstructions blocking the signal. Animals sheltering in shrubs and sub-canopy also benefited from the strongest signals as exposure of the antennae was maximised (very clear signal from animals 15+ m from the ground), but horizontal range close to the ground decreased rapidly when the animals moved away from the stream due to the density of the shrub layer at the study

sites (10–15 m from stream center, depending on steepness of edge and density of vegetation).

Our tags are based on surface-mount SOT-23 Low Distortion Attenuator Diodes (Manufacturer HSMS, model 205B-G Surface-Mount Schottky diode). The antennae are constructed from 9 lb. test fishing leader made up of seven individual strands of stainless-steel wire (any make but bare wire adheres better to the trace on diodes). We use fishing leader wire because it is very flexible and elastic, tending to remain straight rather than assuming a curled shape after being bent, as do many other forms of wire. The length, thickness and material of the antenna affect the resonance of the tracking device, and therefore dictate the strength and range of the signal (Langkilde and Alford 2002). We found that, with the fishing leader wire used here, the best combination of lengths was 13 cm for the cathode wire and 3 cm for the anode wire. Longer wires increased the range of the tag, but were impractical because of both size and weight when attaching the package to very small animals.

We used conductive epoxy (Chemtronics®, Circuit Works® - Conductive Epoxy CW2400) to attach the diode and antenna. Lead-based solder is impractical both because the tiny size of surface mount diodes makes it difficult to solder to them without heating them excessively and because the solder would add substantially to the mass of the final tag. In assembling tags, we first placed double-sided adhesive tape on the work surface, and attached the diode to the tape. We then applied the epoxy in very small amounts to one tip of each antenna wire, and placed this tip on the appropriate trace on the diode. Both antennas are attached to the diode such that they extend away from the same side of the diode in parallel to one another (Fig. 1). We left the assembly undisturbed for 24 h to allow the epoxy to cure, and then removed the assembled tag from the tape. To prevent contact between sharp metallic components or epoxy and the skin of the tracked amphibian, we coated the diode with silicone rubber (Selley's Glass Silicone Sealant®), in which is embedded a length of silicone tubing, oriented at 90° from the long axis of the tag as defined by the antennae; this is used as a harness to attach the tracking device to the frog (Fig. 1).

To minimize the weight of the assembled tag, the silicone in which the diode is embedded is trimmed after drying. We have found that when animals are located in the field, the distal end of the longer antenna is often easily visible, even if the individual is in a retreat site. The distal end of the antenna can be colour-coded using waterproof paint. We coated the color-bands on the antenna with a thin layer of silicone seal to prevent their removal by abrasion in the field.

Tags are attached to frogs by placing the silicone tube around the frog's inguinal region (or 'waist'). The tubing is trimmed so that it just reaches around the frog's waist, with its ends meeting on the ventral centerline. The attachment must be of the correct tightness, which can only be determined with some practice. If attached too loosely, the diode can rotate around the body of the frog to the ventral side, hindering the movement of the animal. If too tight, it can cause abrasion, eventually producing lesions on the frog's skin. Attachment is completed by passing a length of very fine, 100% cotton thread through the silicone tubing, placing the tag on the animal and tying off the thread so that it just draws the ends of the tubing into contact. Using extremely fine, 100% cotton thread ensures that the tag will eventually fall off as the thread deteriorates, in case the animal is not recovered for tag removal (the time taken for the thread to wear off and break is uncertain and would depend on humidity and abrasion).

We used tags constructed as above in densely vegetated habitats (low elevation rainforests of North Queensland, Australia) to track 26 individual frogs (*Litoria rheocola*, mass 0.95–3.30 g in the sampled population; only individuals weighing 1.8 g or more were tracked to meet ethical requirements) for periods of up to 5 days. Diurnally, frogs were found in retreat sites, with 51% found in water and 35% in vegetation near the ground. Apparently normal movement between diurnal retreats and nocturnal activity sites occurred: nocturnally, 100% of frogs moved to vegetation bordering the stream (from shrubs 1–2 m off the ground to some recorded in sub-canopy 12 m). Frogs appeared to climb, jump and swim as they did prior to tracking device attachment (Fig. 2). Tags constructed as we have just outlined have been used successfully by other researchers since our study, focusing on other species (*L. serrata and L. junguy*) as well as *L. rheocola* in lowland rainforests in the Wet Tropics.

Harmonic direction finding, using tags constructed as we outline here, makes it possible to track animals approaching the lower limits of adult vertebrate body size. Our construction method provides a sturdy and stable attachment method for tags that fulfil ethical requirements for tracking very small animals while maximizing the ability to relocate the tags at the greatest possible distances. The continued reduction in size and weight of tracking devices opens up many exciting new opportunities to describe habitat use and movement of particularly minute and discreet organisms, increasing our understanding of the ecology of these poorly understood animals.

Acknowledgments.—We thank the Powerlink Corporation Queensland for funding this research, as well as the Queensland Government and Environmental Protection Agency for supplying the necessary permits. Thanks to James Cook University and ethics committee for approval of our research.

Assessment of Turtle Tracking Technologies in the Brazilian Amazon

Technological developments over the past two decades have contributed tremendously to the study of wildlife ecology, bringing new insights to the management and conservation planning of animal species. In the Amazon, study of Amazonian turtle species using traditional methods has been conducted for 20 years, but researchers have lacked data concerning where turtles go after nesting. The need for essential information not collected by dated methodology called for technological applications to answer specific ecological questions. This review was based upon experience acquired in three ongoing studies of the ecology of turtles in the Amazon Basin.

In this study, three technologies were applied to study freshwater turtles in the Amazon for the first time: Passive Integrated Transponder (PIT), Very High Frequency radio (VHF), and satellite radio. For decades, ecologists and wildlife biologists have used a technique called mark-recapture, in which animals are captured and then externally marked or tagged in some way with a personal identification number before being released (Gibbons and Andrews 2004). With the advent of PIT technology, animals may be internally tagged with the advantage of not being affected by external factors or not affecting intraspecific social interactions or altering behavior toward tagged individuals (Gibbons and Andrews 2004; Jackson and Bunger 1993). PIT tags are tiny identification chips which are injected into specimens for permanent identification and have been retrieved with great success for more than 20 years (Boarman et al. 1998). The tags are injected into the caudal musculature of the turtle and read by an external reader which bounces an electronic signal off the tags to identify them.

In VHF radio telemetry, a small electronic device is attached to an individual, allowing it to be accurately tracked and monitored using a receiving unit (Marshall et al. 1971; Schemnitz and Owen 1969). Over the years, the decrease in size of the electronic components, circuit boards, and batteries has resulted in transmitters smaller than 0.4 g, enabling the study of smaller species and even hatchlings (Warnock and Takekawa 2003).

The third and more recent technology used to track animals

is the satellite system. This technology became an operational tool for tracking the long-range movements of animals in the 1980s. Applying satellite system technology initially represented a challenge because most animal species were smaller than the biggest pixel of public access satellites data (0.6 m) and the passage times of satellites over the equator in the Amazon were so infrequent that animal positions could not be determined. However, with the advents of ARGOS (Advanced Research and Global Observation Satellite), the tracking of animal movement patterns became more feasible (Gillespie et al. 2008).

These three technologies have been important in field studies driven by the need to answer new questions regarding the ecology of Amazonian turtles in order to develop rigorous conservation measures. However, these devices are generally designed and tested to work successfully in temperate climates where they have been developed. Conditions in the Amazon, a tropical rainforest environment, are sufficiently different to affect the use of these devices.

In this paper we report the use of technical equipment to identify and track freshwater turtles in the Amazon region and provides advice on how devices that may be designed for temperate areas can successfully be used in tropical climates. Advantages, disadvantages, problems, and possible improvements of using technologies to track animals in tropical areas are discussed.

MATERIAL AND METHODS

Study areas.—The Mamirauá Sustainable Development Reserve (MSDR; 01.8347°S, 65.7053°W) is located on the floodplain between the Middle-Solimões and Japurá rivers (Fig. 1). Mamirauá is a reserve covering an area of 1,124,000 ha (Raeder and Bernhard 2003). In this area, we conducted field work from 1996 to 2004 using PIT tags with *Podocnemis sextuberculata* and *Podocnemis unifilis.*

Rio Quimicuri (00.7069°S, 63.2325°W) is part of the Rio Negro Basin (Fig. 1) (De la Ossa 2007). The Quimicuri River is a blackwater river with well-defined high and low water seasons (Castillo et al. 2004). In this river, individuals of *Peltocephalus dumerilianus* were captured from 2001 to 2006 and fitted with VHF transmitters.

Reserva Florestal Adolpho Ducke (3.1333°S, 60.0667°W) is located 25 km E of Manaus (Fig. 1) and has gradually become isolated from adjacent forests by the development of villages and agricultural activities (Magnusson et al. 1997). In this reserve, VHF transmitters were used to monitor *Platemys platycephala* in 1993.

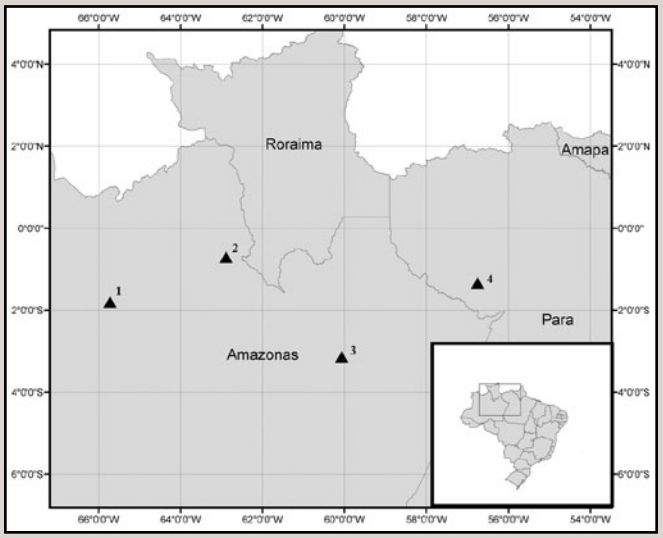

FIG. 1. Localization of the four study sites in the Amazon Basin with the Brazilian location on the right corner: (1) Mamirauá Sustainable Development Reserve, (2) Rio Quimicuri, (3) Reserva Florestal Adolpho Ducke, (4) Rio Trombetas.

The Trombetas Biological Reserve (1.3333°S, 56.75°W) is in northwestern Pará state, northern Brazil (Fig. 1). The Trombetas meanders generally southward for 760 km and joins the Amazon River in Obidos at Oriximina (Goulding et al. 2003). This area was selected for its large population of *Podocnemis expansa*, which is now listed as Critically Endangered by the IUCN and is the most threatened turtle species in the Brazilian Amazon. In this river, *P. expansa* and *P. unifilis* were studied at different times between 1989 and 2009, when all three technologies were used.

Equipment and brands applied.—Devices and species studied are detailed in Table 1. PIT tags were purchased from AVID Northwest Marine Technology, Inc. PIT tags are glass-encased electronic transponder tags that are inserted into turtle muscle. PIT tags have been used for over 20 years to permanently identify individual animals. The tag has no battery so the microchip remains inactive until read with a scanner. The scanner sends a low frequency signal to the microchip within the tag providing the power needed to send its unique code back to the scanner and positively identify the animal. Passive tags are designed to last longer than the life of the animal, providing a reliable, long-term identification method.

VHF-monitored radio tracking equipment was purchased from AVM Instrument Company, Ltd. The system consisted of a handheld Yagi 4-element antenna and receiver to collect signals from deployed transmitters. The system remained fully operational 24 h a day while the batteries were working. The modulation format used in this study is AM (amplitude modulation). Expected transmission lifespans range from 10–14 months for the 120 g transmitters deployed on the turtles.

TABLE 1. Locations of this study, detailing the devices used to mark and track freshwater turtles species in the Brazilian Amazon.

Location	Equipment	Species	No. of devices
RDS Mamiraua	PIT tags	*Podocnemis sextuberculata*	240
Rio Quimicuri	VHF Transmitters	*Peltocephalus dumerilianus*	10
Rio Trombetas	PIT tags	*Podocnemis expansa*	8150
		Podocnemis unifilis	2000
	VHF Transmitters	*Podocnemis expansa*	53
	Satellite Radio	*Podocnemis expansa*	10

		Phrynops rufipes	8

FIG. 2. Insertion of a pit tag in a hatchling of *Podocnemis expansa* in Rio Trombetas. Tags were inserted right below the carapace of the turtles.

FIG. 3. Insertion of a pit tag in hatchling turtles. Applicator needles supplied by the pit tags companies are too large to be used, so a 2 mm hole was made by piercing the skin with the point of a blood collector.

TABLE 2. Battery life expected by the manufacturers and actual results obtained in this study in the Brazilian Amazon.

Technology	Expected Life	Average life obtained (min. – max.)
Satellite radio	12 months	8.2 months (6–10)
VHF radio	12 months	8.3 months (8–11)
PIT tags	unlimited	Over 15 years

Satellite monitored radio technology requires satellite transmitters, known as Platform Transmitter Terminals (PTTs). In this study the PTTs were purchased from Sir Track, Ltd., and the satellite data were transmitted via satellite using the ARGOS System. The ARGOS environmental satellite system currently consists of six polar satellites orbiting at altitudes of 740–850 km with 5000 km visibility circles (footprints). During the satellite orbit, this footprint sweeps in a wide swath around the earth, receiving signals from the PTTs. The number of daily passes over a PTT increases with latitude. At the earth's poles, a PTT is within the visibility circle of the six satellites approximately 80 times per day, whereas at the equator (e.g., the Amazon region), a PTT can be visible perhaps 20 times per day (ARGOS 2008). Our study recorded a maximum of six passes per day, which is every four hours.

Transmitters can be programmed to send signals to satellites at periodic intervals. In salt water, transmitters are activated only when the turtle is at the surface and deactivated when submerged by a saltwater switch. Now new technology has been developed which includes a freshwater switch as well, which will increase the battery life by many months, since the transmitter will only be activated when the turtle is at the surface. To increase the life of the transmitter in our initial use in freshwater, the PTTs remained active for 24 h only for the first three months, then were active from 0600–1200 h every four days. Expected transmission lifespans for the 1800 g transmitters we deployed on 10 turtles ranged from 10 to 12 months. ARGOS satellites pass over about once every 4 h and if the turtle is on the surface of the water, both temperature and position are recorded.

Attachment of the equipment.—The PIT tags were inserted dorsally into the base of the tail just below the carapace in adult and juvenile turtles, using the injecting applicator needle supplied with the tags (Fig. 2). However, these applicator needles are too large to be used with hatchling turtles. Instead, a 2-mm hole was made by piercing the skin with the point of a blood collector (Fig. 3). The tag was inserted through the hole deep into the tail musculature using a fine tipped Inox 25 forceps. All material was sterilized first in an ethyl alcohol bath. After inserting a tag in an animal, the local area was cleaned using iodine and protected by liquid band aid.

Transmitters, both VHF and satellite, were glued to the carapace of the turtle with Turbolit, a marine product used for patching holes underwater in marine vessels. Two resins are mixed together with wet hands to form a uniform pliable paste. The turtle shell is prepared by scrubbing with soap and water and then roughened with sandpaper to ensure that the glue will hold the transmitter onto the turtle. The paste is then molded onto the front of the turtle shell, followed by pressing the transmitter into the paste and folding the paste over the transmitter to make a secure bond. The turtle is kept out of water for 24 h to make sure the gel has dried before release (Fig. 4). Prior to the discovery of Turbolit in 2005, VHF transmitters were first glued to the turtle carapace on the 9th–10th marginal scutes with epoxy quick-drying cement. When fixed in place, four 3-mm holes were drilled in these scutes, two on each side of the transmitter, and the transmitter was secured with 2 mm diameter stainless steel wire looped through the holes and around the transmitter. A cover of duropoxy was used to form a cap over the transmitter and wire such that it appeared as a tumor on the shell of the turtle with no jagged edges to catch on branches.

RESULTS

The devices used in this study were functional. However, because of the tropical rainforest environment of the Amazon, the high temperature decreased battery life. Regardless of the equipment efficiency, we also found problems with the discarding of equipment by poachers who caught turtles for illegal sale as food. Table 2 displays real battery life time in the Amazon environment compared to expected battery life, showing that the battery life obtained for VHF radio and satellite radio equipment was much lower than expected.

PIT tags.—The efficiency of PIT tag technology was difficult to analyze because it was impossible to distinguish unmarked

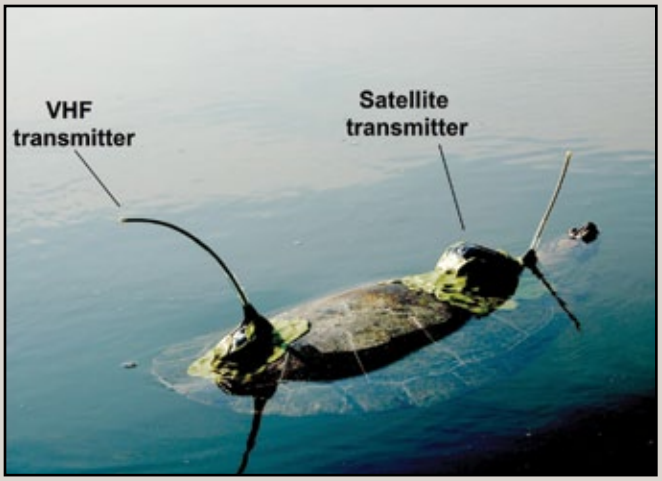

FIG. 4. Satellite and VHF Transmitters glued on the carapace of the turtle (*Podocnemis expansa*) with Turbolit. The paste is molded onto the turtle shell, followed by pressing the transmitter into the paste and folding it over the transmitter to make a secure bond. In this picture the turtle has just been released.

FIG. 5. *Podocnemis expansa* recaptured at the nesting beach with satellite transmitter attached four years after deployment, demonstrating the bonding potential of Turbolit glue. The PTT was easily pried off the turtle shell, leaving the carapace undamaged.

turtles from turtles whose PIT tags had ceased to function. However, from the 2000 PIT tags implanted in *P. unifilis* hatchlings in Rio Trombetas, seven were recovered still functioning. Three were found 13 years following implantation and four after 15 years. In addition, five PIT tags were encountered by people while eating cooked turtles. The tags no longer functioned, suggesting that the heat used in cooking the turtle meat destroyed the tags.

VHF radio.—A total of 76 VHF radios with a putative 12-month battery life were attached to turtles. Of these 76 VHF radios, eight were removed from the study by poachers. Eight were lost because of long-distance migration immediately following release and 16 either failed after three months operation or because turtles moved out of range. Most of the transmitters stopped working because the battery died: 36 after eight months, two after nine months, four after 10 months, and two after 11 months (Table 2).

In the study of *Peltocephalus dumerilianus*, two VHF radios worked for nine months and four for 11 months. All four VHF radios attached to *Platemys platycephala* worked for 10 months. With *Podocnemis expansa* in Rio Trombetas, of a total of 52 non-poached turtles monitored by VHF radios, seven were lost after three months because of the turtles entering deep into the flooded forest. Thirty-six VHF radios functioned for eight months. Finally, eight *P. expansa* were lost within five days after they had a VHF radio attached, by migrating far downstream from the nesting areas, moving up to 45 km in two days.

Satellite radio.—Of the 10 satellite transmitters used in this study, two were removed by turtle hunters almost immediately and one following eight months of use. Of the seven not discarded by local people, six suffered a reduced battery life, six failed to provide location signals after eight months, and one failed after 10 months (Table 2).

Two transmitters were recovered at the nesting beach four years later, still attached to turtles, demonstrating the bonding potential of Turbolit. Upon recapture, the PTTs were easily pried off the turtle shells with a Swiss army knife blade, leaving the carapace undamaged (Fig. 5).

DISCUSSION

Technology plays an important role in the monitoring of animal species. The choice of the technology to be applied depends mainly on the range of the species, its habitat, and the objectives for which the technology is used. Any decision to invest in and implement a technology should be based on an analysis of costs and benefits for a project to be successful. Any technology used must be appropriate for the operating conditions. This is true for the technology design, the resources required to implement it, and its ability to withstand challenging conditions. High temperatures and high humidity in remote field locations in areas such as the Amazon affect electronic devices negatively. Impacts of field conditions, such as dust, heat, humidity, water, and energy should be considered.

We strongly suggest that when choosing identification markers one consider consistency, standardization, and availability of a common database between researchers and organizations studying the same animal groups or animals studied. In addition, tag frequencies, manufacturers, and tag readers may not always be compatible. We suggest always using products compatible with those used in previous studies.

However, even though the VHF radios did not function for 12 months, the transmitters functioned satisfactorily until the batteries died, giving constant signals with an acceptable signal range.

The reduced lifespan of the satellite transmitters also was due to the high temperatures which reduced battery life. This could be improved by using devices which only give signals when they can be captured by the satellite and are more adapted to high temperatures. For this study the amount of energy consumed by the transmitter had not been calculated correctly, even though it was known that the transmitters consume more energy in hot climates. The transmitters were programmed based on ocean-going animals where the water is much colder than in the Amazon. It was not realized that the current drain would be so much higher in the Amazon heat. Now, reprogramming the two recovered transmitters on a different cycle with new batteries will enable them to function with the same number of batteries for the full 12 months or longer. This type of transmitter was used for the first time in a freshwater ecosystem and in the tropics. New transmitters can be programmed differently, using new calculations based on temperatures in the tropics, so that

they can produce signals for the entire year. There is also now available a freshwater on/off switch, such that the transmitter is only activated when it is at the surface out of the water, which will greatly conserve battery life.

We recommend that researchers collect data 24 h a day at the initiation of each study. After the movement patterns and activity patterns are determined, the transmitters may be programmed to operate only during the optimal time to send signals to satellites. If the turtles are relatively stationary for a period of time, battery life may be optimized by only activating the transmitter 6 h a day every four days, allowing for the collection of data for a longer time. The discarding of equipment by poachers complicates use of technology, because one cannot ascertain whether loss is due to emigration, equipment failure, or poaching. In this study we documented some transmitters that were disabled by poachers because some were recovered where the poachers had discarded them. The PTT was cut off the turtle and probably destroyed or thrown into the water, from which signals cannot be received. Local fishermen told us of one PTT that was recovered from where it was taken off a turtle. If the battery dies, signals will not be received either, but both the VHF signal and the satellite transmitter are not likely to die at the same time.

In the case of VHF radios applied to *Podocnemis expansa*, seven turtles were simultaneously marked with VHF and satellite technology. VHF signals were lost when these individuals entered flooded forest, while satellite technology continued to provide data.

APPLICATIONS AND RECOMMENDATIONS

Satellite radio versus VHF radio.—Locations derived from satellite tracking helped to delineate the reproductive, flooded, and dry season ranges of turtles to migration sites. Such information is essential to establish where females observed at a given beach live during the remainder of the year. For long-distance migrants, satellite tracking is a useful tool for monitoring migration routes. However, for species with limited migration or dispersal distances, satellite tracking may not be productive, while a VHF radio tracking system would provide better data

For some species the use of both methods might be appropriate, using satellite tracking to study their ranges, habitat use, and migratory routes and the VHF system to study habitat patch utilization and other fine-scale ecological interactions. When working with both technologies simultaneously, the satellite radio provides coordinates that facilitate approximating the general location of the individual so that the VHF radio may yield its exact position.

For an animal that does not move often, VHF is more precise and cheaper than satellite tracking. This system successfully collects continuous presence and absence data and turtle mortality data from local people and also estimates the amount of time that turtles spend on or near nesting beaches.

In the Amazon, the satellite system has shown high performance in tracking animals. However, Mantovani et al. (2003) reported that this method is not appropriate for tracking animals in fragmented areas and small rivers like those in the southeast region of Brazil. This was not a problem in tracking turtles in the Amazon Basin because, although there may be errors of hundreds of meters in their exact locations, the large size of rivers in the Amazon makes up for any error in the tracking location.

PIT tags versus plastic tags.—This study has confirmed that PIT technology is a reliable and promising method for identifying and monitoring individuals over long periods of time and is very efficient as a tool to study capture-recapture, movement, abundance, survival, and recruitment. In addition, the use of passive tags for animal identification and research provides many benefits, including the reduction of error in recording data, rapid data collection, and long-term reliability. They allow researchers to permanently mark animals internally without altering external appearance and eliminating negative impact on animals as they have little or no influence on growth rate, behavior, health, and predator susceptibility.

Previous experience indicates plastic tags were not as successful as the PIT tag system because plastic tags were lost faster and within four years of being marked. No turtles were recaptured with a plastic tag after four years.

Disadvantages and limitations.—Satellite and VHF-monitored radio tracking: The use of the satellite system is worth the expense because there is no need to track the animals in the field by boat or airplane which increases the costs. However, because turtles are a source of traditional local cuisine, they are heavily harvested by locals and consequently some of our equipment attached to these turtles is destroyed. Since a VHF radio is cheaper, it is therefore recommended if the species can be tracked and the signal received within the turtle's home range. In addition, VHF works better in fragmented areas, as already reported by Mantovani et al. (2003).

Passive Integrated Transponders.—The primary disadvantage of this technique is the cost (approximately US $4 per tag plus the cost of the tag reader). The standard version of this type of tag is 10–14 mm long and as the tag is inserted into the caudal musculature, experience and care are required in this procedure. However, when compared to plastic markers, PIT tags are still worth the cost.

Acknowledgments.—This study was supported by the Instituto Nacional de Pesquisas da Amazonia (INPA), Conservation International (CI), World Wildlife Fund (WWF), Comunidade Europeia, Wildlife Conservation Society (WWS), Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq), Fundacao de Amparo a Pesquisa do Estado do Amazonas (FAPEAM), Mineracao do Rio Norte, Instituto Brasileiro do Meio Ambiente e dos Recursos Naturais Renováveis (IBAMA), and Instituto Chico Mendes (ICMBio). The study was done under the auspices of IBAMA permits. We thank all the students who spent their time and effort helping with the monitoring of the turtles.

Using Tattoos to Mark *Apalone ferox* for Individual Recognition

Researchers use numerous methods to mark turtles for individual recognition (Ferner 2007; Plummer 1979). The most widely used method for hard-shelled turtles is shell notching (Cagle 1939) or a variant thereof. Other techniques used for marking hard-shelled turtles include passive integrated transponders (PIT; Buhlmann and Tuberville 1998; Rowe and Kelly 2005; Runyan and Meylan 2005) and metal tags attached to the carapace (Obbard and Brooks 1981) or flippers (Balasz 1985). Techniques that have been employed for soft-shelled turtles include hole punching (Doody and Tamplin 1992), inserting plastic spaghetti tags (Dreslik 1997), branding (Woodbury and Hardy 1948), notching the edge of the carapace (Breckenridge 1955; Plummer 1977, 2008), and tattooing (Breckenridge 1955). Overall, few studies have examined the effectiveness of tattooing as a marking technique for reptiles but there are reports of limited success in snakes (Woodbury 1948) and turtles (Balazs 1978; Breckenridge 1955).

In 2007, we began capturing and marking the soft-shelled turtle *Apalone ferox* in a spring-run complex located in Wekiwa Springs State Park, Florida, USA. Turtles were captured by snorkeling or with baited hoop nets during biannual, five-day sampling sessions. Captured individuals were tattooed with numbers (beginning with "1") on the underside of the carapace posterior to each rear leg (Fig. 1). The areas to be marked were dried, blotted with alcohol, and tattooed using a battery-operated tattooing gun (Permanent Marker Cordless Tattoo'r). After tattooing, the areas were rinsed with alcohol, allowed to dry, and then coated with a thin layer of antibiotic ointment. The tattooing process required ca. 10 minutes to complete. Tattooed turtles were kept dry for ca. 1 h before release. The process caused minimal bleeding (Fig. 1), which stopped before turtles were released. Touch-up tattoos were reapplied to all individuals recaptured during subsequent sampling sessions. Photographs of individuals were taken and in 2009 we began PIT tagging turtles to verify tattoo effectiveness.

Fig. 1 illustrates typical changes as observed in the tattoo of one turtle. The initial tattoo was dark (Fig. 1A) and when the individual was recaptured during the same five-day sampling session, it exhibited a dark and legible tattoo (Fig. 1B). Seven months after original marking, the tattoos had faded, but a clearly-visible scar reflecting the number remained (Fig. 1C). Touch-up tattoos were reapplied and the turtle was released. Five months after remarking, the tattoo had again faded but the scar remained clearly visible (Fig. 1D). (Marks were more apparent in the field than is shown in photographs.) To date, 39 individuals have been tattooed, of which 12 were recaptured and remarked during a second (subsequent) sample, five were recaptured and remarked during a third sample, and two were recaptured and remarked during a fourth sample. Table 1 summarizes the time elapsed (in days) between marking and recapture. All recaptured individuals exhibited a visible tattoo or scar and the numbers have always been discernable. The long-term effectiveness of tattoos is supported by four recaptures ca. 1 year after marking, one recapture ca. 2 years after marking, and one recapture ca. 2.5 years after marking (Table 1). The most faded tattoos observed during the study were similar to the marks in Figs. 1C and 1D. PIT tags have aided in the verification of eight recaptures (Table 1) during later sampling sessions. In one instance (turtle 18), a PIT tag was lost or malfunctioned and the animal had to be re-tagged. The tattoo, along with body measurement data and previous photographs, positively identified this turtle.

Using body measurements, photographs, and PIT tags, we consider it unlikely that any turtles were misidentified. While fading of tattoos may make tattoos inappropriate for studies with long periods (several years) between samples, our data indicate that studies with at least annual sampling can employ tattoos.

During this study, *A. ferox* with carapace damage sufficient to obscure marks from notching or hole punching have been observed. To minimize mark loss, animals were tattooed twice in locations which are subjected to minimal wear. Breckenridge

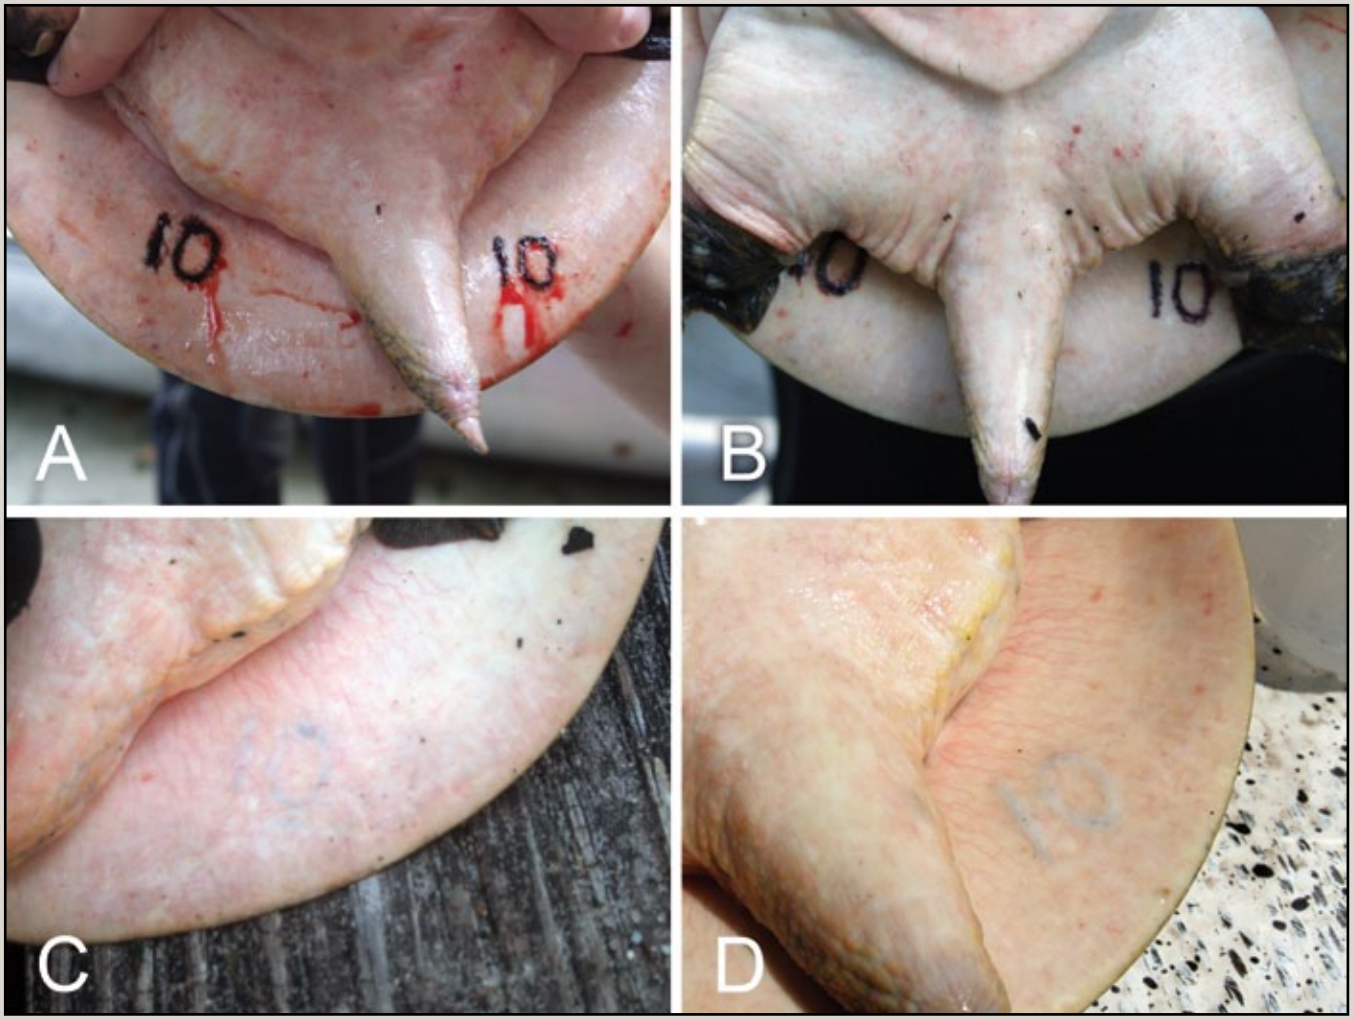

FIG. 1. Appearance of a tattoo mark in *Apalone ferox* A) immediately after the initial tattooing process; B) after recapture ca. 24 h after the initial tattooing process; C) 213 days after the initial tattooing process; and D) 349 days after the initial tattoo process and 136 days after its secondary tattoo.

(1955) placed tattoos in a high-wear area, the plastron. This may, in part, explain why he never recognized any recovered individuals as marked.

Tattooing does not require the removal of tissue, making it less intrusive than carapace notching or hole punching (Breckenridge 1955; Doody and Tamplin 1992; Plummer 1977, 2008). Tattooing is less expensive to employ than PIT tagging, which can cost ca. US $400 for a scanner (Rowe and Kelly 2005; Runyan and Meylan 2005) and ca. US $4–6 for each tag. The tattooing device used in this study cost ca. US $50 and required only new batteries, ink, and needles (which came with the device).

Apalone ferox is still a relatively little-known species compared to other North American freshwater turtles. We attribute this, in part, to the difficulty of marking these animals. Our method provides researchers with an inexpensive, effective technique for marking soft-shelled turtles. We hope this method will encourage more research on soft-shelled turtles.

Acknowledgments.—We thank the past and current staff of Wekiwa Springs State Park and the Florida Department of Environmental Protection for providing support and making this research possible. Thanks to Brian P. Butterfield for his role in initiating the study at Wekiwa Springs and for providing valuable comments on a draft

An Effective Method for Transporting Hellbenders (*Cryptobranchus alleganiensis*)

The Eastern Hellbender (represented by two subspecies, *Cryptobranchus alleganiensis alleganiensis* and *C. a. bishopi*) is an impressively large, strictly aquatic salamander endemic to eastern North America (Petranka 1998). Hellbenders can grow to 74 cm in total length and are gray, brown, or dark green with a dorsoventrally flattened body and a laterally compressed, keeled tail. Although hellbenders have lungs, they are cutaneous respirators and require pristine, cool, swiftly moving streams and rivers with high levels of dissolved oxygen that equates to approximately 100% saturation (Nickerson et al. 2002). Cutaneous respiration is aided by the hellbender's conspicuous, undulating vascular lateral skin folds, which increase surface area for gas exchange.

Populations of hellbenders have declined throughout their range (Foster et al. 2009; Petranka 1998; Wheeler et al. 2003) because of habitat alteration resulting from mining and agricultural activities, collection for the pet and bait trades, and potentially from chemical contamination (Foster et al. 2009; Petranka 1998). As a result, the species is listed as Near Threatened by the IUCN and is listed as Special Concern in New York State. The New York State Department of Environmental Conservation (NYSDEC) has acknowledged that without intervention, the hellbender in New York is expected to continue its decline (Bell et al. 2010). In an attempt to address this, a statewide recovery plan has been written by a team of experts from within and outside the NYSDEC (Bell et al. 2010); the plan includes headstarting of wild-collected hellbender embryos. The NYSDEC and the Buffalo Zoo have spearheaded an effort to develop captive rearing or headstarting efforts for the Eastern Hellbender in New York State. The Wildlife Conservation Society (WCS)/Bronx Zoo was presented with the opportunity to help with this effort through fostering a portion of the larvae, which will be reared in captivity for two years at the Bronx Zoo prior to their return to their natal river in western New York State. However, we had to find a safe and effective way to transport them from Buffalo, New York to the Bronx (an approximately 640 km journey) in July, the hottest month of the year in the New York Metropolitan Area with an average monthly high temperature of 29°C (National Climatic Data Center; www.ncdc.noaa.gov).

The particularly high oxygen needs of this species required that we manufacture a reliable system for maintaining low

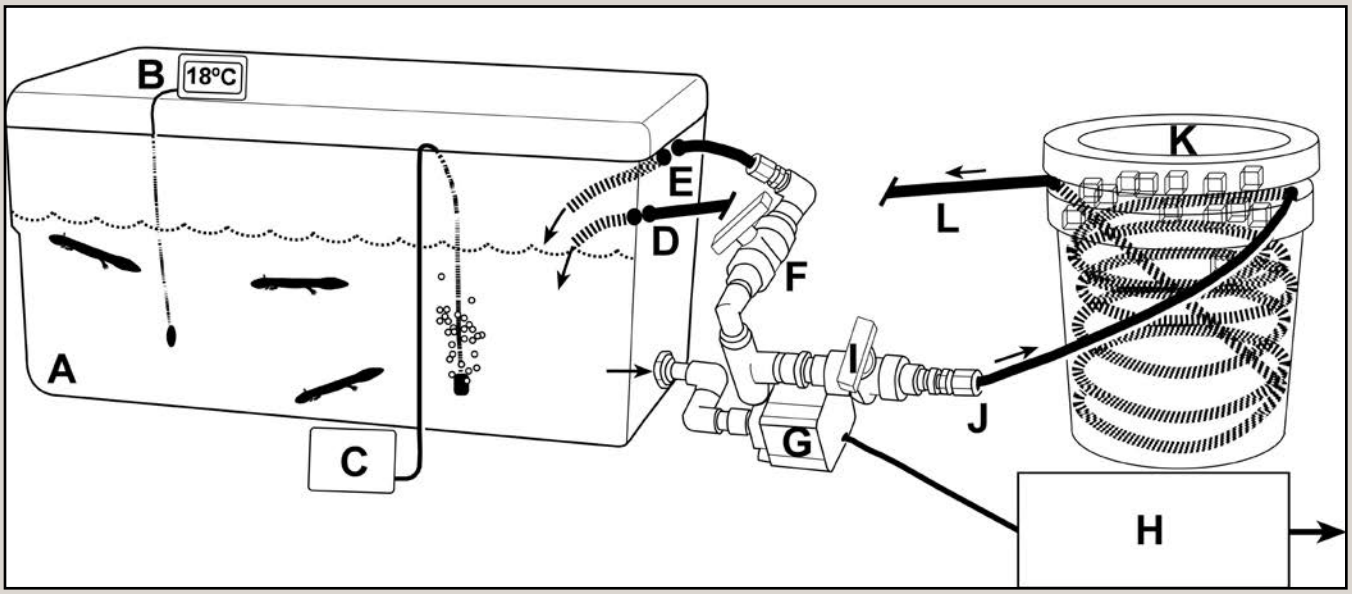

FIG. 1. The hellbender transportation device. Note that parts are not drawn to scale. Product brands are provided in the text. A) A 114 liter-capacity beverage cooler. Approximately 20 nine-month old juvenile hellbenders were transported in each container with the cooler lid closed during transport to keep the water cold. B) An external digital thermometer with an internal probe. The probe was secured underwater to the wall of the cooler with a suction cup that is provided with the product. C) A battery-operated aerator with an air stone; two were used for each cooler. D) The return hose from the heat exchanger, which passes through the wall of the cooler. E) The return hose from the pump, which passes through the wall of the cooler. F) The tank circulation valve, which can be closed completely to form a closed loop between the heat exchanger and the tank. To make the tank water warmer, this valve should remain fully open, while Valve I is shut off completely, thus shunting water flow to the heat exchanger and maintaining water current and oxygenation of the system. G) A 115-volt water pump. The pump is connected to a power converter (H). The power converter converts 12-volt DC power to 115-volt AC power, allowing us to run the AC water pump off of the vehicle's battery via the cabin power source or cigarette lighter. I) The heat exchanger valve. This valve can be completely opened or closed or closed partially to regulate the rate of flow of the water through the heat exchanger. The more open this valve is, the more quickly the water will cool. J) The outflow tube leading to the heat exchanger. K) The heat exchanger consists of a 431.8 cm long, 1.27 cm outer diameter HDPE plastic tube that is coiled inside a five gallon bucket filled with ice. The lid is placed tightly onto the bucket. The greater the number of hose coils inside the heat exchanger, the greater the surface area and efficiency of the heat exchanger; however hose length is negatively correlated with flow rate. L) The return or outflow hose from the heat exchanger to the hellbender tank. For illustrative purposes, the hose here is shown as an incomplete line but in reality it is continuous with D.

temperatures and high dissolved oxygen during transport. Although there are many published reports and accounts on the monitoring of wild *C. alleghaniensis* populations and proven methods of capture (e.g., Foster et al. 2008; Humphries 2007; Nickerson and Krysko 2003; Williams et al. 1981), there are very few notes and published reports on how to manage their safe transport and captive care (Indiviglio 2010). Moreover, although there are commercially produced refrigerated devices for transporting fish, they are prohibitively expensive. Herein we describe a simple and cost-effective method we developed to transport hellbender larvae.

Transporting cool-loving hellbenders in the middle of a North American summer presents logistical challenges. Originally, we investigated the possibility using a commercial airline to transport the hellbenders from Buffalo to the Bronx. However, because they breathe through their skin and through external gills as larvae, ground transportation was the safest option as when aboard a plane, it would have been impossible to observe them and to intervene in order to provide supplemental oxygen if needed. Only by driving the hellbenders could we carefully monitor their progress and troubleshoot oxygen levels if necessary. This problem necessitated the planning and manufacture of an efficient transportation container that could simultaneously cool and oxygenate the animals for their relatively long journey to the Bronx Zoo.

We constructed two transportation devices, which each housed approximately half of the 41 gilled hellbender larvae. Each hellbender transportation container was manufactured with a Coleman® Xtreme 114 liter-capacity cooler. Each cooler was filled with approximately 70 liters of water, which was brought from the filtered water supply at the Bronx Zoo. The water system at the Bronx Zoo's Amphibian Recovery Center (ARC) incorporates ozone treatment, carbon and cloth-bag filters, removes chlorine and chloramines, and reduces phosphate levels from the New York City municipal water. Water temperatures in the hellbender room at the zoo are maintained at 18°C during the summer. In order to acclimate the hellbenders during their ride to the Bronx Zoo, our goal was to maintain transportation containers at 18°C throughout the round trip.

Each cooler (A) was plumbed with a pump (Model 5® utility pump, 115 volt AC; Aquatic Ecosystems, Inc.), which was connected with PVC piping to the drain spigot of the cooler with a 2cm (3/4") exterior bulkhead and internal strainer (Fig. 1). The pump was powered with the transportation vehicle's battery, which is accessed with a voltage transformer (DC to AC voltage transformer with 12 volt DC input and 120 volt AC output with a power output of 700 watts or 5.8 amps; McMaster-Carr) connected to the vehicle's dashboard power source. The pump (G) circulated the water from the cooler to a heat exchanger and through the cooler. The heat exchanger (K) was made from a

20-liter plastic bucket filled with ice. Through this bucket, a 430 cm-long, coiled HDPE plastic hose (1.27 cm outer diameter) circulated the hellbenders' water. Our heat exchanger had five coils of water-circulating hose inside the bucket. Two PVC ball valves regulated the flow of the water through the system. Valve F continuously regulated the flow rate of water through the cooler. The other valve (I) regulated flow through the heat exchanger. The temperature of the water holding the hellbenders was regulated by adjusting Valve I. When Valve I was shut off completely, then water flow was only circulated through the cooler through Valve F and gradually became warmer. In contrast, when Valve I was fully open, it allowed maximum flow through the ice-filled heat exchanger, and decreased the temperature of the water inside the cooler (A). Thus, through closing or opening Valve I partially or completely, we could manage the water temperature very effectively, to within one or two degrees of our target temperature. The Coleman® beverage cooler also insulates very well and is highly efficient at maintaining stable temperatures. In each transportation container, two battery-powered aerators (Penn-Plax® Silent Air B10), each with airline hose and an airstone, were used to further aerate the water (C). The coolers were placed onto a sheet of insulating foam to help buffer them from the van's hot floorboards and also to prevent them from sliding on the floor of the van.

On 13 July 2010, two of us (JP and JW) traveled to the Buffalo Zoo, New York to transport 41 hellbender larvae to the Bronx, New York. The round trip was made the same day and was approximately eight hours in each direction including rest stops. The highest outdoor ambient temperature along the route that day was 29°C. The van's cabin was air conditioned with the ambient temperature fluctuating from 21°C to outdoor ambient. On our way to pick up the hellbenders we let the system run in order to make any necessary adjustments and to ensure that the optimal temperature could be maintained throughout the trip. Prior to their release into the water of the transport device, the hellbenders were suspended in plastic tropical fish bags for at least twenty minutes until the temperature inside the bag was at equilibrium with that of the transport container.

Both on the trip to Buffalo, New York, and during our return to the Bronx, we were able to maintain a nearly constant (~18°C) water temperature inside the transport containers. Approximately two, 2.2 kg bags of commercially prepared ice were used to fill the heat exchanger described above. The ice, purchased from convenience stores, was changed out twice during each leg of the trip.

Upon arrival at the Bronx Zoo, the hellbenders were transferred immediately from the coolers to their new 75-liter (20-gallon long) aquaria (1–2 hellbenders per aquarium) in a biosecure room in the Amphibian Recovery Center. The water temperature of their new aquaria was nearly identical to that of the water in which they were transported. All 41 hellbenders made the trip safely and are, as of publication, doing well at the zoo. This method was very effective for the transportation of hellbenders and may prove useful in the transport of other aquatic amphibians, particularly montane species such as frogs of the genus *Telmatobius*. The number of animals that can be carried in each device is dependent upon the dissolved oxygen (DO) needs and body mass of the particular species. It is recommended that users of this device research the physiological parameters required of the species being transported. In this case, we set up our device, allowed it to run for several hours, and used a digital meter to determine the DO levels in each to ensure that they would be within reasonable limits for transporting 41, 7 cm-long larvae.

Acknowledgments.—We thank Gerald Aquilina and Penny Danielewicz of the Buffalo Zoo for assisting us with acquiring the hellbenders from their institution (and assisting us with changing out a damaged tire on our transport van). Thanks also to Kenneth Roblee of the NYDEC for sending out the call for area zoos to participate in the hellbender headstarting effort. We are grateful to Chandra Jessee for her generous support of the Bronx Zoo's amphibian conservation efforts.

Captive Management and Reproductive Biology of Latifi's Viper (*Montivipera latifii*) (Squamata: Viperidae) at Razi Institute and Tehran University in Iran

Latifi's Viper or Lar Mountain Viper (*Montivipera latifii*) is a small, mountain-dwelling venomous snake occurring in Iran in Tehran Province (lar Damavand, Ab-Ask, Firuzkuh, Gajere, Gachsar and Afjeh) (Rastegar-pouyani et al. 2008). This species is found only in Iran and has been considered at risk since 1979, when there was concern about the possible extinction of this viper (Andén and Nilson 1979). Construction of an enormous earthen dam called Lar Dam inundated the habitat in the late 1970s and it appeared that the snake was forever lost. In 2000 an isolated population was found in the upper Lar Valley in the Elburz Mountains. In 1983 the snake was listed as Endangered and its future has not improved (Groombridge 2010; Red List of IUCN 2010).

In older Iranian literature on venoms and snakebites many *Vipera* species, including *M. latifii*, were referred to *Vipera xanthina* or *V. xanthina* ssp. (Mallow et al. 2003). Nilson et al. (1999) erected the subgenus *Montivipera* within the genus *Vipera*, which later was elevated to genus rank (Joger 2005). Nine taxa are contained in *Montivipera* including *M. latifii*. All are high-altitude mountain dwellers. We consulted Andrén (1986), Andrén and Nilson (1979), Latifi (1985), Mallow et al. (2003), Mertens et al. (1967), Nilson and Brodmann (1987), and Phelps (2010) for descriptions of *M. latifii*, especially color and pattern morphs (Fig. 1). Color photographs showing three of these morphs are available (U.S. Dept. of Defense Intelligence Document 1991).

Andrén and Nilson (1979) characterized the habitat of *M. latifii* as high alpine steppe located at an elevation of 2000–4000 m. The Lar Valley is surrounded by high mountains and is essentially closed. Adults were found in well-drained, sparsely vegetated rock habitats. We measured air temperatures in July 1973 and June 1976 (daytime 28–35°C, 10–13°C immediately after sundown, 0–5°C at night). Most of the time, the snakes were underground, perhaps in response to low temperatures. Behrooz (2009) described the habitat: mountainous areas, grasslands, rocky outcrops, and shrubland (Fig. 2).

The maximum length is 79 cm and the length of the tail is 5 cm (Farzanpay 1989; Latifi 1991). Andrén and Nilson (1979), Mallow et al. (2003), and Mertens et al. (1967), described four distinct color and pattern morphs and two are shown here from Latifi (1985; Fig. 1). Litter size varies from 3–10 neonates (Andrén and Nilson 1979; Latifi 1985; Mertens et al. 1967). The diet for this species in the wild consists of insects, grasshoppers, lizards, and mice (Behrooz 2009).

Today this species is highly threatened and has vanished from many parts of its range due to both the destruction of its natural habitat (Behrooz et al. 2009) and the overcollecting of snakes for the production of antivenin (Nilson 2008). The Razi Institute started in 1958 to produce antivenin and the first serum was issued for therapeutic use two years later; venom was extracted from 9397 vipers (Latifi 1978). In 1984 Latifi described venom extraction from nearly 8750 (additional?) snakes and described antivenin production at Razi Institute the following year. Mallow et al. (2003) describe the production of antivenin in detail. There are three main reasons for setting up a colony of *M. latifii* at Razi Institute: to eliminate the need to purchase snakes from local collectors for antivenin production, to increase numbers by improved captive management and expanded captive breeding, and to decrease mortality rates. At Tehran University 12 specimens are currently maintained to study reproductive biology and will be released after studies have been completed.

FIG. 2. Three views of habitat of Latifi's Viper (*Montivipera latifii)* in Lar Valley, Iran, now a national park. This viper is at risk due to increased human visitation and collection by snake hunters. The Razi Institute continues to produce antivenin to counteract potential snakebites.

CAPTIVE MANAGEMENT

Very little information is available on reproduction and growth under laboratory conditions. One of the reasons may be due to the low number of specimens in captivity. Mamet and Kudrjavtsev (1995) have published information on the breeding of *Montivipera latifii* at the Moscow Zoo.

In 2008 and 2009, 26 Latifi's Vipers were captured in the Lar Valley (Alborz Mountain, Kakamega Forest, Damavand District, Tehran Province, Iran) to form the nucleus for a captive breeding program at Razi Institute and Tehran University. The first group was collected in 2008 and consisted of eight female specimens that appeared to be gravid. The second group was collected later that year and consisted of six specimens (two females and four males). The snakes in these two groups were held at Razi Institute. The next year 12 individuals (six females and six males) were collected and maintained at Tehran University.

Our snakes had coloration and pattern variation as described by Andrén and Nilson (1979; Table 1); the markings were most often vertebral lines and zig-zags (Fig. 1). Variants were found with light grayish-yellow ground color with mid-dorsal dark brown spots and two diagonal dark brown to black stripes on each side of head. A few had pale yellow ground coloration with a pattern of black and white small spots.

TABLE 1. Parturition in captive Latifi's Vipers (*Montivipera latifii*) in 2008.

Number of neonate	Beginning emergence of neonates / egg masses from cloaca	Complete emergence of neonates / egg masses	Total time between initial appearance and total emergence of neonates/egg masses (min)	Intervals between births and egg mass extrusions (min)
1 (Neonate with spinal defect)	0950 hr	1000 hr	10	—
2 (Infertile egg mass)	1006 hr	1012 hr	6	6
3 (Infertile egg mass)	1022 hr	1028 hr	6	6
4 (Healthy neonate)	1103 hr	1122 hr	19	35
Mean			10.25	11.75
Total time = 102 min				

Data are presented here reflecting our two-year study on behavior, reproduction, and growth under laboratory conditions. Ettling and Marfisi (2002) described male-male combat behavior in *Montivipera wagneri* and *M. raddei*. Although many male *M. latifii* were maintained in the same enclosures during our study, we did not observe this behavior. Greene et al. (2002) described parental behavior in *Vipera berus*: "Some authors have claimed that Adders (*Vipera berus*) aggregate with their young for up to several days after birth, and that the young seek cover under the female when approached closely…Conversely, several experienced researchers at the conference on which this volume is based have not observed female *V. berus* attending their young (S. Anderson, C. Andrén, T. Madsen, and R. Thorpe, pers. comm.)." We have not observed this parental behavior in *M. latifii*.

The 26 individuals captured from the wild were housed in special vivaria with environmental parameters (temperature and humidity) similar to the native habitat as described below.

The enclosures.—In August 2008, two adult pairs were housed in one glass vivarium measuring 120 cm L × 45 cm W × 50 cm H with aluminum mesh on the top and front. Two males were put into another glass enclosure of the same size with aluminum mesh on the top and rear. In 2009, five enclosures were redesigned to increase space and improve ventilation (120 cm L × 60 cm W × 50 cm H).

Two of the new vivaria with increased floor space were used to house four adult pairs and two adult pairs, respectively. The substrate was peat moss. Pieces of broken flower pots were available as hiding places.

Temperature, humidity and lighting.—An incandescent light bulb (40 watt) was used as a heat and light source with an automatic timer set to duplicate daylight cycles. The thermal gradient ranged from 30–32°C beneath the lamp to 26–28°C at the far end. Every week the enclosures were sprayed with warm water. The humidity level prior to the spraying was 35% and increased to 50% after spraying was done. The relative humidity averaged 40–50%.

Disinfection and quarantine.—With any new animals coming into captivity, care must be taken to prevent cross contamination and any infectious disease should be treated in a timely manner (Murphy and Armstrong 1978). Quarantine procedures were strictly followed. The incoming vipers were quarantined for a minimum of four weeks, strictly following established protocols, as recommended by Ross and Marzec (1990), but we note here that due to the danger of Ophidian Paramyxovirus, recommendations today stress that quarantine should be extended to a minimum of 90 days (Elliott Jacobson, pers. comm.). To eradicate ectoparasites, the vipers were dusted with Opigal powder, a product used in Iran to treat fowl for mites, ticks, and lice.

Sex determination and marking.—The sexes of the animals were tentatively assigned based on tail length/body length ratio initially and later validated by probing male copulatory organs as described by Laszlo (1975) and Toriba and Hirabayashi (1995). The variation of unique and distinct markings among individual animals was used to keep track of males and females during the hibernation period and for tracking the feeding history of each snake. In addition, nail polish was painted on tails to track individual snakes; this approach was used as it was easily implemented, clearly distinguishable, and was not harmful to the marked individual (see Murray and Fuller 2000 for discussion on marking techniques).

Food and feeding.—Laboratory rodents were the most commonly available food items and were selected to decrease the risk of endoparasitic infection (Chanhome et al. 2001). Newborn and adult mice (*Mus musculus albinus*), and newborn rats (*Rattus norvegicus berkennhout*) were offered once a week; the vipers did not accept the lizards (*Mesalina watsonana, Eumeces schneiderii*) that were offered. In 2009 the food items were supplemented with the multivitamin "Rep-Cal Herptivite Multivitamin" (Rep-Cal Research Lab, Los Gatos, California). There was competition during feeding. In some cases snakes struck each other during predatory episodes.

Generally, gravid snakes lose normal body weight during the reproductive cycle due to birth of young and long periods without food during gestation. Body weight and accumulation of fat is necessary to enable the process of follicular maturation and neonate production. In 2008 the newly captured snakes did not accept food and the body weight of males and females declined; hence, females likely had no fat reserves for reproduction. The next year snake weight increased because the vipers were feeding with regularity. In 2009 the newly captured gravid viper started to take food earlier than usual, which indicated a need to increase the required body weight and fat for the next breeding cycle as described by Vyas (2002).

Availability and diversity of food are important for captive reproduction (Ambu et al. 1986; Kudrjavtsev et al. 1993). When food items were supplemented with multivitamins in 2009, this change had a positive effect on weight gain and resulted in more complete shedding of snakes (Grubant et al. 1973; Igolkina et al. 1989; Mamet and Kudrjavtsev 1995).

Nursery cage and neonatal husbandry.—Neonates were placed into separate plastic boxes that were ventilated by drilling holes on each side and lid. The box size was 30 × 10 × 10 cm and contained an inverted flowerpot (as a hiding place), paper substrata, and a water bowl. The temperature in one part of the box was kept at 28–30°C during the daytime by using an incandescent bulb (20 watt). The other part was kept at 26–27°C, and the

temperature and humidity at night corresponded to the seasons. The temperature was 22–24°C at night, accomplished by simply opening the windows. Spray-misting was done as needed in the cooler parts to ensure that the humidity remained at 40–50%.

Ecdysis.—Successful shedding depends largely on environmental temperature and the amount of food intake. The time between the onset of milky blue eyes and complete shedding averaged one to two weeks. Intervals between shedding ranged from one to several months. Shedding seemingly depended on temperature but might also have been influenced by the amount of moisture to which the snake was exposed. Adequate moisture was provided by spraying water into cages as needed. When snakes did not shed properly, they were soaked for ca. 20 minutes in water to facilitate ecdysis.

Hibernation.—According to some authors the most important aspect contributing to successful reproduction in captivity is artificial hibernation (Buzhansky and Kudryavtsev 1982; Grubant et al. 1973; Mamet and Kudryavtsev 1995; Strelkov 1986). Because this viper is found in mountainous areas where the temperatures remain seasonally cold, hibernation seems necessary for this species. In Lar Valley, the snake is found near bodies of water in the spring and summer where the temperature is higher than in other parts of the range and where slope and rocky habitat provides shelter (Behrooz 2009). In the lab after the vipers had been offered food for several months, the animals were placed into hibernation. On 15 October 2008 males and females were separated; the snakes were no longer offered food but water was provided. After a period of seven weeks the temperature of the cages was decreased to 10°C and the lamp was extinguished. The cooling period was 76 days. The temperature remained between 8–10°C throughout this time span. On 19 February 2009 the lamp was turned back on and natural sunlight penetrated the room; light was gradually increased from zero to three hours per week. After four weeks light was at 12 hours. On 20 March 2009 males and females were placed together.

In April 2009 we collected 12 additional vipers from Lar Valley that had emerged from hibernation in the wild. These snakes were sent to Tehran University where they were hibernated the following autumn, kept at temperatures ranging between 6 and 8°C. In March they emerged from hibernation.

RESULTS

First birth.—Of the eight gravid females collected on 22 July 2008 for Razi Institute, all but one had reproductive complications: stillborn young or infertile egg masses. On 30 August 2008, a lined-pattern gravid female was coiled at the center of the cage near the water container. During parturition muscular contractions of the posterior trunk were evident. The tail showed noticeable movements in an upward and downward plane. The first snake born had a lined pattern and died 2.5 h after birth because of a spinal chord defect. The second and third masses passed were infertile. The fourth neonate had a zig-zag pattern. Thus only one young snake was normal and healthy. Periods of time between births and passage of egg masses varied. Table 1 indicates the time for the entire process of parturition which lasted 102 min. After birth the spent female crawled to the cleaner corner of the cage, possibly to avoid the afterbirth. The young one crawled around the cage, shed on the fifth day, and started to feed soon after ecdysis. Newborn dead mice were the first prey items accepted. Tare and Renapurkar (1992) observed parturition in captive Russell's Viper (*Daboia russelii*) which was similar to what we observed with this female.

Second Birth.—On 24 April 2009, a group of 12 specimens were collected and housed at Tehran University. Of the six females collected in April 2009, one of the zig-zag patterned females spent almost all of the time under the heat lamp and was inactive. The posterior 1/3 of female's body was enlarged, indicating gravidity. On 21 August 10, neonatal vipers were born, and were weighed and measured: weight (3.8–4.9 g, mean = 3.8 g, variance = 0.1316); length (16.0–18.4 cm, mean = 17.5 cm, variance = 0.4921). Our snakes were smaller and lighter than those recorded by Mamet and Kudrjavtsev (1995), likely because our litter was larger. All had zig-zag patterns. Eight of ten neonates shed their skin in 5–7 days and two others shed after two months. After the first shedding none of the neonates accepted food readily so they often had to be stimulated to eat or forcibly fed. Moving food in front of the snake with long forceps stimulated a feeding response (see Murphy and Campbell 1987 for details). Neonates could be encouraged to accept small mouse parts such as a tail or leg. This was done by lightly touching the tip of the snake's snout or tail with the food item until a strike was induced whereupon feeding commenced. After one year the snakes accepted newborn mice without intervention by the caretakers. The survival ratio of neonates after one year was 50%.

In November 2009 the snakes were placed in hibernation. After emergence from hibernation on 30 March 2010 they were placed together to elicit courtship and copulation. During May courtship behavior by the male was noted but although copulation was not observed we are hopeful that future captive reproductive events will occur.

In summary, we conclude that artificial hibernation, type and diversity of food, vitamins, adequate fat reserves in females, and laboratory conditions based on environmental features duplicating the natural habitat of this species contributed to growth and courtship in the laboratory.

Acknowledgments.—This project could not have succeeded without the devoted technical help of Tehran University staff. We are grateful to H. Torabian, K. Falah, N. Mosafa, Rostami, A. Shirvani, R. Behrooz, and N. Nasirimoghadam for their help and encouragement. For various courtesies, we thank Kraig Adler, Judith Block, Elliott Jacobson, Polly Lasker, Roy McDiarmid, Tim Perry, and Wulf Schleip. We would also like to gratefully acknowledge the Iranian Department of Environment (DOE) for their financial support in conducting this research.

Ranavirus Prevalence in Amphibian Populations of Wise County, Virginia, USA

Several factors have been linked to catastrophic amphibian declines, including habitat alteration and pathogens (Semlitsch 2003; Stuart et al. 2004). Ranaviruses (Family: Iridoviridae; Genus: *Ranavirus*) are one particular group of pathogens linked to massive amphibian die-offs (Daszak et al. 1999; Gray et al. 2009a; Green et al. 2002). Despite the evidence of ranaviruses becoming an emerging disease (Storfer et al. 2007), we still know relatively little concerning its geographic distribution among amphibian species. Rather, most recent amphibian pathogen studies center on *Batrachochytrium dendrobatidis* (Ohmer and Bishop 2011). However, *B. dendrobatidis* should not be the only pathogen that warrants investigative attention, as others are quite capable of exerting deleterious effects upon amphibian populations (Duffus 2009). Herein, we examine the occurrence of ranavirus infections in amphibians (including urodeles and anurans) present in the southern Appalachian Mountain areas. Ranaviruses have been associated with some mortality events in this region (Green et al. 2002), yet much of this area (and, much of North America in general) remains unsurveyed despite it being a hotspot for urodele diversity and endemism (Petranka 1998).

We sampled for ranavirus by collecting toe clips from dipnet and hand-caught amphibians of Wise County, Virginia, USA, from April to September 2010. Wise County is located in southwest Virginia (Fig. 1). Wise County covers approximately 1050 km^2, including approximately 3 km^2 of water coverage. Being in the midst of the Appalachian Mountains, Wise County has tremendously heterogeneous habitats along elevation gradients. Sample collections were conducted in the preferred habitats of all the amphibian species known to occur within the county (see Mitchell and Reay 1999 for complete amphibian species occurrence list) at various times of the day/night to increase the probability of capture success. We surveyed several regions of Wise County, including both private (with permission of landowner) and public land. However, the majority of sampling occurred on public-use land—mostly in various regions of the Jefferson National Forest. Indeed, a large portion of Wise County is part of the Jefferson National Forest. Our surveyed regions include: Cave Springs Recreation Area and Stone Mountain Trail (both near Big Stone Gap, Virginia); Guest River Gorge Trail, the Clinch River (and its numerous branches), and Little Stony Falls (all near Coeburn, Virginia); High Knob Recreation Area and Flag Rock Recreation Area (both near Norton, Virginia); Red Fox Trail and Pound Lake (both near Pound, Virginia); Cane Patch Recreation Area, Phillips Creek Recreation Area, and the main campus of the University of Virginia's College at Wise (all near Wise, Virginia). We are not reporting exact locations due to the vulnerability of these endemic urodele species in the area. No individual was sampled more than once during our approximately 121 person-hours in the field.

FIG. 1. Map of Wise County, Virginia, USA.

In order to minimize cross contamination between collected toe clip samples and between field sites, all equipment and instrumentation used were rinsed in a 10% bleach solution, followed by a dechlorinated tap water rinse between every use/sample acquisition. In addition, nitrile gloves were worn and replaced between each collected and handled amphibian. Individual toe clips were immediately preserved and stored in 1.0 ml of 70% ethanol in a 2.0 ml screw-cap vial. DNA extractions were completed using Promega® Wizard Genomic DNA Purification Kits (Promega® Corporation, Madison, Wisonsin, USA), as per manufacturer's instructions. Extracted DNA products were amplified using Fisher® BioReagents exACTGene PCR Kits (Fisher Scientific®, Fair Lawn, New Jersey, USA), using PCR primers #4 and #5 described in Mao et al. (1996 and 1997) that amplify an approximately 500 bp region of the ranavirus major capsid protein. PCR was performed using the following protocol slightly modified from Greer and Collins (2007) and Greer et al. (2009): an initial denaturation at 94°C for 5 min; denaturation

TABLE 1. Ranavirus prevalence in the amphibians of Wise County, Virginia, USA.

Species	No. infected / total sampled	Prevalence of infection (95% confidence interval)
Caudata		
Desmognathus fuscus	7 / 12	0.58 (0.32–0.81)
Desmognathus monticola	8 / 12	0.67 (0.39–0.86)
Desmognathus ochrophaeus	0 / 1	0 (0–0.79)
Desmognathus quadramaculatus	3 / 3	1 (0.44–1)
Eurycea cirrigera	10 / 21	0.48 (0.28–0.68)
Eurycea longicauda	2 / 3	0.67 (0.21–0.93)
Eurycea lucifuga	1 / 4	0.25 (0.05–0.7)
Notophthalmus viridescens	1 / 9	0.11 (0.02–0.44)
Plethodon cinereus	0 / 3	0 (0–0.56)
Plethodon glutinosus complex	4 / 15	0.27 (0.11–0.52)
Plethodon richmondi	0 / 5	0 (0–0.43)
Anura		
Anaxyrus americanus	0 / 6	0 (0–0.39)
Hyla chrysoscelis	0 / 9	0 (0–0.3)
Pseudacris crucifer	0 / 2	0 (0–0.66)
Lithobates catesbeianus	2 / 10	0.2 (0.06–0.51)
Lithobates clamitans	0 / 1	0 (0–0.79)
Lithobates palustris	1 / 2	0.5 (0.09–0.9)
Lithobates sylvaticus	0 / 1	0 (0–0.79)
Total	39 / 119	0.33

at 94°C for 1 min, annealing at 55°C for 1 min, and extension at 72°C for 1 min, each cycled 35 times. PCR products, including a positive control and negative controls (an extraction control and a DNA-free PCR mixture control) for each gel, were visualized on 1.0% agarose gel stained with ethidium bromide in 1X TAE buffer under ultraviolet (UV) light. All DNA extractions were amplified and run in duplicate. A positive test was recorded only if each sample duplicate yielded the targeted ~500 bp fragment. If sample duplicates had conflicting results (i.e., a positive and a negative) or if both duplicates yielded a negative result, its respective sample DNA was re-extracted and PCR was conducted in duplicate twice more. All equipment and materials used for DNA extraction and PCR amplification were sterilized under UV light prior to and between uses.

A total of 119 samples were collected from 18 amphibian species in Wise County, Virginia, USA (Table 1). Overall, 39 of 119 (approximately 33%) samples tested positive for *Ranavirus*, of which 36 of 39 (approximately 92%) were caudates and 3 of 39 (approximately 8%) were anurans. However, no sampled individual showed external signs of ranavirus infection, such as erythema or edema. Three samples (two *E. cirrigera* and one *Lithobates catesbeianus*) were excluded from analysis after multiple extractions and amplifications still yielded mixed PCR results. However, other samples from these two species tested positive.

Our data are the first to show the presence of ranavirus infections in amphibian populations of Wise County, Virginia, USA. In addition, we show *Desmognathus fuscus*, *Eurycea cirrigera*, *E. longicauda*, *E. lucifuga*, and the *Plethodon glutinosus* complex as new plethodontids capable of acting as ranavirus hosts. However, it is not the first report of ranavirus in southern Appalachian Mountain amphibians. Gray et al. (2009b) reported the first occurrences of ranavirus infections in lungless salamanders (Plethodontidae) from Tennessee, with a prevalence of 81%. While our data do not suggest nearly as high prevalence among plethodontids (approximately 44%), our low sample size per species (thus, our subsequently large confidence intervals; Table 1) coupled with the use of toe-clips from numerous field locales may warrant caution when discussing true prevalence. Toe-clips have a false-negative rate of ~12% relative to livers in field samples (St-Amour and Lesbarreres 2007) and recent infections can be difficult to detect in peripheral tissues (Greer and Collins 2007), so we likely underestimate true prevalence. However, unless dead individuals were found in the field (and they were not), we did not desire to euthanize any amphibians—particularly some of the salamanders because of their endemism or due to ongoing mark/recapture studies.

In summary, we report the first occurrence of ranavirus in Wise County, Virginia, USA. Continual monitoring of ranavirus occurrence and possible infection in amphibian populations of the southern Appalachians should be part of future efforts because that region houses several endemic amphibians, particularly plethodontid species. In addition, we report five new plethotontids (*D. fuscus*, *E. cirrigera*, *E. longicauda*, *E. lucifuga*, and the *P. glutinosus* complex) as ranavirus hosts. To date, only 15 plethodontids, including our new accounts, have been reported as ranavirus hosts (see Gray et al. 2009b for other known plethodontid hosts). With more than 370 described plethodontid species, additional work investigating which species can act as ranavirus hosts is warranted and encouraged. In addition to investigating possibly new locations and new amphibian host species for ranaviruses, emphasis should also be placed on assessing ranavirus pathogenicity (Duffus 2009). Pathogenicity is not often addressed in amphibian disease investigations despite its importance to amphibian population dynamics (Duffus 2009). Studies addressing this knowledge gap are essential for furthering our understanding of amphibian host-virus interactions and molecular characteristics of potentially novel ranaviruses in these hosts.

Acknowledgments.—We thank K. Jones and R. Woodard for generously assisting with several aspects of PCR work, including controls and various equipment and materials. Thanks are due to the several private landowners that allowed us to survey their property. J. Brunner and two anonymous reviewers improved earlier versions of this manuscript. Partial funding for this project was in the form of an undergraduate Fellowship in the Natural Sciences to SRAD, provided by the Department of Natural Sciences at the University of Virginia's College at Wise (UVA Wise). Amphibian collections were done in accordance with protocol #BIO.201011.DLC from the Institutional Animal Care and Use Committee at UVA Wise and Virginia Scientific Collection Permit #039466.

Detection of *Batrachochytrium dendrobatidis* on Amphibians in Pursat Province, Cambodia

Cambodia, along with other Southeast Asian countries, has an enormously diverse flora and fauna, but past turmoil has had a significant and disparaging impact on wildlife (Loucks et al. 2009). Despite the struggles and hardships faced by the country, some of the country's wildlife, particularly reptiles and amphibians, are still being discovered. A recent survey of amphibians and reptiles in the east of Cambodia, for example, has led to the discovery of various new species of frogs, snakes, and lizards (Stuart et al. 2006). New herpetofauna, particularly anurans, were also discovered in southwest Cambodia where surveys yielded new species in isolated areas of the Cardamom Mountains, implying the species had no prior exposure to humans and thus were not directly impacted by their activities prior to their classification (Grismer et al. 2007, 2008; Ohler et al. 2002). Global declines of amphibians have been linked to human activities resulting in habitat destruction and alteration (Alford and Richards 1999), accelerated global environmental change (Gibbs and Breisch 2001), or interspecific competition and hybridization (Kiesecker and Blaustein 1997), as well as to the emerging infectious disease chytridiomycosis caused by the fungus *Batrachochytrium dendrobatidis* (*Bd*) (Berger et al. 1998). The presence of *Bd* has been confirmed worldwide (www.Bd-maps.net), including Southeast Asia (Fisher et al. 2009b). The first studies on *Bd* in Southeast Asia have been performed within the last decade starting with island states or countries such as Hong Kong, Indonesia, Taiwan,

and Japan (Fisher et al. 2009b; Kusrini et al. 2008; Lehtinen et al. 2008; Rowley et al. 2007), eventually including detection from mainland countries like Thailand, South Korea, and China (Bai et al. 2010; McLeod et al. 2008; Wei et al. 2010; Yang et al. 2009). Consequently, the reported detection of *Bd* in the continent of Asia is a very recent event, and thus literature on this subject currently remains preliminary given the amphibian biodiversity.

The goal of our study was to increase the knowledge of the distribution of *Bd* in mainland Southeast Asia. We sampled amphibians for *Bd* occurrence in the Cardamom Mountains, in and around the small village of Pramouy in Pursat province, Cambodia (Fig. 1), with three levels of urbanization. The level of human influence was categorized as high (areas where people frequently congregate), medium (areas with minimal human disturbance), or low (areas where humans very rarely visit). Sample locations included creeks and other small pools of water in the village of Pramouy (high, 12.3036167°N, 103.1008333E; 240 m elev.), alongside a forest road about 10 km outside Pramouy (medium, 12.10175°N, 103.10405°E; 400 m elev.), and within an isolated forest atop Mount Tumpor in the Cardamom Mountains (low, 12.3740333°N, 103.05675°E; 1100 m elev.).

We sampled 144 amphibians at the three locations (village of Pramouy, N = 64; Forest Road, N = 18; Mount Tumpor, N = 62) during a five-day period starting on 25 April 2010 (Table 1). All captures were performed either at dawn or dusk using small nets. No amphibians showed clinical symptoms of chytridiomycosis (e.g., lethargy, lack of righting reflex, excessive sloughing of skin). For each individual, a sterile cotton swab was run ten times over each of the four feet, the medial and ventral area of the rear legs, on each of the sides from groin to armpit, and on the ventral surface of the body of each individual (Kriger et al. 2006). Swabs were placed in 2-mL cryotubes and kept at 4°C prior to molecular analyses.

DNA was extracted from cells on swabs using the Wizard Genomic DNA Purification kit (Promega, Madison, Wisconsin) in accordance with the protocol for extraction from animal tissue, and *Bd* was detected and quantified using a TaqMan quantitative real-time PCR (*q*PCR) assay according to Boyle et al. (2004). Samples were tested in triplicate, using 20-µL reactions containing 10 µL *q*PCR Fast-Mix™ (Quanta Biosciences, Gaithersburg, Maryland), PCR primers ITS1-3 Chytr and 5.8S Chytr at 900 nM, probe Chytr MGB2 at 250 nM, and a single µL of template DNA. A single µL of sterile water facilitated the negative control for each reaction (also performed in triplicate). Analyses were performed in an Eppendorf *realplex*^{2} thermocycler (Eppendorf, Hauppauge, New York) using a 50°C incubation for 2 min, followed by 95°C for 10 min, and finally 50 cycles of 95°C for 15 s and 60°C for 1 min (Boyle et al. 2004). Quantification of *Bd* was based on a standard curve created using a serial dilution of a standardized DNA control with known copy number (CSIRO Livestock Industries, Geelong, Australia).

We detected *Bd* on 59 of 144 (41%) individuals tested (Table 1). Of amphibians captured within the village (high human impact), along the forest road (medium human impact), and atop Mount Tumpor (low human impact), 36%, 50%, and 44% of the amphibians were *Bd*-positive, respectively. These values were statistically not different from each other (Pearson's Chi-squared test in R 2.11.1; $\chi^2 = 1.4475$, p = 0.48). The number of *Bd* genomic equivalents (GE) per individual ranged from 0 to 373.4 GE, and averaged 27.9 GE. The average (± SE) numbers of *Bd* GE on amphibians from the village, along the forest road, and atop Mount Tumpor were 25.2 GE (± 40.6), 22.3 GE (± 31.2), and 31.9 GE (± 56.0), respectively.

We demonstrate that *Bd* was prevalent in amphibians regardless of the perceived level of human influence among the environments, revealing approximately half of the amphibians tested from each environment were infected with the fungus. However, none of the amphibians had identifiable symptoms of chytridiomycosis. The dynamics and consequences of *Bd* infection are complex, and not well understood. Whereas there are numerous studies describing how introduction of *Bd* can quickly decimate a population of amphibians (Daszak et al. 1999; Lips et al. 2006; Pounds et al. 2006), there are also studies that show amphibians can be infected with the fungus with no apparent detrimental effects. In those cases the infected frogs act as asymptomatic carriers; examples of such carriers include the American Bullfrog, *Lithobates catesbeianus,* and the African Clawed Frog, *Xenopus laevis* (Daszak et al. 2004; Weldon et al. 2004), two species that have been introduced to non-native habitats in many parts of the world. In addition, it has been speculated that the fungus could have sub-lethal effects, for example it may stunt the growth of amphibians, or amphibians may be temporarily affected (Kriger et al. 2007; Walker et al. 2010). The potential

seasonality of infection rates have been noted (Gaertner et al. 2009; Kriger and Hero 2007). We sampled during the dry season which might have influenced *Bd* detection rates in our study. It is also possible that the genotypes of *Bd* were hypovirulent and thus less lethal than others (Fisher et al. 2009a), or that the critical threshold density for *Bd* on amphibians was not reached and thus amphibians were not showing symptoms of chytridiomycosis (Vredenburg et al. 2011). Also, it is known that amphibians have innate immune defenses to counter pathogens like *Bd* in the form of antimicrobial peptides secreted on the skin (Ramsey et al. 2011; Rollins-Smith et al. 2003; Rollins-Smith and Conlon 2005; Woodhams et al. 2007). Studies have indicated that immune-suppressed amphibians are more susceptible to acquiring diseases from their environment due to inhibited or decreased production of peptides during periods of stress or from pesticide use (Davidson et al. 2007; Rachowicz et al. 2005). We did not assess either sublethal effects on individuals or the stress levels of the amphibians in this study.

Anthropogenic influence appears to have played a significant role in the global distribution of *Bd* (Fisher et al. 2009b; Skerratt et al. 2007). Recently, it has been suggested that trade of American Bullfrogs for human consumption might be a key component in the dissemination of *Bd* in China as well as across the globe (Bai et al. 2010). The concept of pathogen pollution refers to anthropogenic movement of pathogens into new geographic locations via domestic and wild animals, products and materials (Daszak et al. 2001). This might explain how amphibians collected from the village and forest road were positive for *Bd* as human interaction with fauna may be frequent, however, it does not adequately explain how amphibian populations sampled atop Mount Tumpor first encountered the pathogen. Mount Tumpor, at least the area where we collected, is free of human influence, except for scientific expeditions (the nearest settlement being >1 km). However, *Bd* transmission pathways across landscapes are little understood. Previous studies have shown amphibians living in pristine environments have undergone population declines associated with *Bd* (Kolby et al. 2010; Lips et al. 2004; Puschendorf et al. 2006). Other studies indicate *Bd* prefers habitats at higher altitudes, cooler climates, and rainy or wet environments, which parallel the environmental conditions on Mount Tumpor (Drew et al. 2006; Rohr and Raffel 2010; Ruiz and Rueda-Almonacid 2008). If *Bd* were introduced as a novel pathogen to our study area in Cambodia by anthropogenic pathways at an earlier time, it might have spread to achieve its current distribution by other vectors of transmission.

In summary, we have reported the incidence of *Bd* in Cambodia across three environments that have different levels of human influence. We found there to be no difference in *Bd* infection with respect to the predicted level of human activity among the three sampling areas. To date *Bd* has been detected in almost every country bordering Cambodia (Bai et al. 2010; McLeod et al. 2008; Wei et al. 2010; Yang et al. 2009), suggesting that *Bd* has probably crossed the borders of Laos, Vietnam, and Myanmar despite the current absence of detailed reporting from those nations. Future studies are needed to both: 1) address the prevalence of *Bd* in these countries (Rowley et al. 2010), as well as in other Asian countries, in order to fully understand the dissemination of this pathogen and to maintain the well-being of amphibians worldwide, and 2) monitor these amphibian populations long-term in case their infection rates change and symptoms start appearing.

Acknowledgments.—We are very grateful towards Fauna & Flora International, Cambodia Program, and the Royal University of Phnom Penh, and more specifically to Neil Furey, Kris Menrith, K'Noy, Kah and Ken and Verena Wilson for their assistance with this project and our work in Cambodia. Our study was supported by the Ken and Verena Wilson Foundation, the Alexander Stone Endowment in Genetics, the Department of Biology at Texas State University-San Marcos, and the National Science Foundation (GK-12 grant No. 0742306). The research was carried out in compliance to the rules overseen by the Texas State Institutional Animal Care and Use Committee (IACUC, permit 0915 0520 14), and within country coordination and oversight by Neil Furey, Head of Academic Development at Fauna and Flora International (Cambodia).

Detection of *Batrachochytrium dendrobatidis* in Frogs from Different Locations in Cambodia

The recently emerged infectious disease chytridiomycosis caused by the fungus *Batrachochytrium dendrobatidis* (*Bd*) has been implicated as a significant contributor to amphibian population declines worldwide (Fisher et al. 2009; Kilpatrick et al. 2009; Schloegel et al. 2006). The presence of *Bd* has been confirmed for all continents with amphibians (Fisher et al. 2009), with a considerable number of reports available for Australia (Bell et al. 2004; Hero and Gillespie 1997; Kriger et al. 2007), Africa (Goldberg et al. 2007; Hopkins and Channing 2002; Lane et al. 2003), Europe (Bosch et al. 2001; Bovero et al. 2008; Garner et al. 2005; Walker et al. 2010), and North and South America (Bonaccorso et al. 2003; Davidson et al. 2003; Herrera et al. 2005; Ouellet et al. 2005; Rothermel et al. 2008) (see also www.Bd-maps.net). The presence of *Bd* also has been confirmed for Asia, however, reports are relatively recent and the surveys remain limited to a small number of countries (e.g., China, Indonesia, Japan and South Korea) (Bai et al. 2010; Goka et al. 2009; Kusrini et al. 2008; Yang et al. 2009).

We have recently demonstrated the presence of *Bd* on amphibians in the southwestern part of Cambodia, including an isolated area of the Cardamom Mountains, with comparable prevalence of infected amphibians observed in environments impacted by various degrees of human activities (Mendoza et al. 2011). With 40–50% of all amphibians from these environments being positive for *Bd*, prevalence of infection resembled that found in amphibians from South Korea (39%) (Yang et al. 2009), but were much higher than those reported for amphibians from natural environments in China, Japan and Indonesia with 15%, 4% and 3%, respectively (Bai et al. 2010; Goka et al. 2009; Kusrini et al. 2008). To validate our high prevalence of *Bd* infection, we expanded our sampling to sites throughout Cambodia, and included amphibians obtained from market environments that, as for those in pet shops (Goka et al. 2009), have been shown to display higher frequency of infection than those in natural environments (Bai et al. 2010). We also examined the pattern of *Bd* haplotypes among our samples.

Creeks and small pools of water were used as sampling sites in three locations which included the capital city Phnom Penh (11.5193167°N, 105.0100667°E), the Angkor Center for the Conservation of Biodiversity (ACCB) (13.67805°N, 104.0261°E), and the city of Kratie (12.4875333°N, 106.0159833°E). Market frogs were obtained from Sihanoukville (10.62325°N, 103.53285°E) (Fig. 1).

FIG. 1. Cambodia locations where amphibians were sampled for *Batrachochytrium dendrobatidis*, including Phenom Phen, ACCB, Kratie, and Sihanoukville Market.

A total of 238 amphibians were obtained across the four locations (Phnom Penh, N = 77; ACCB, N = 65; Kratie, N = 66; Sihanoukville Market, N = 30) during one-day sampling trips in 2009 (25 May, 8 June, 19 June, and 13 June, respectively) (Table 1). None of these amphibians showed symptoms of chytridiomycosis (e.g., lethargy, lack of righting reflex, excessive sloughing of skin). Individual amphibians were sampled with a sterile cotton swab following the instructions outlined in Kriger et al. (2006), and swabs placed in 2 ml cryotubes and kept at 4°C until DNA extraction with the Wizard® Genomic DNA Purification Kit (Promega, Madison, Wisconsin) using the protocol for extraction from animal tissue. A nested PCR approach was used to test for *Bd* (Gaertner et al. 2009). This approach was based on the initial amplification of the 5.8S rRNA gene and the flanking internal transcribed spacer (ITS) of all fungi (White et al. 1990). A portion of the purified amplification product of this reaction was then used as template in a second *Bd*-specific PCR reaction (Annis et al. 2004). These second reactions were then analyzed for the presence of 300-bp amplicons (Annis et al. 2004) using gel electrophoresis (2% agarose in TAE buffer) (Sambrook et al. 1989).

Of the 238 amphibians tested, a total of 86 (36%) were positive for the 300-bp fragment, indicating the presence of *Bd* (Table 1). At Phnom Penh, 9 amphibian species were caught, and *Bd* was detected on individuals from 5 species with an average

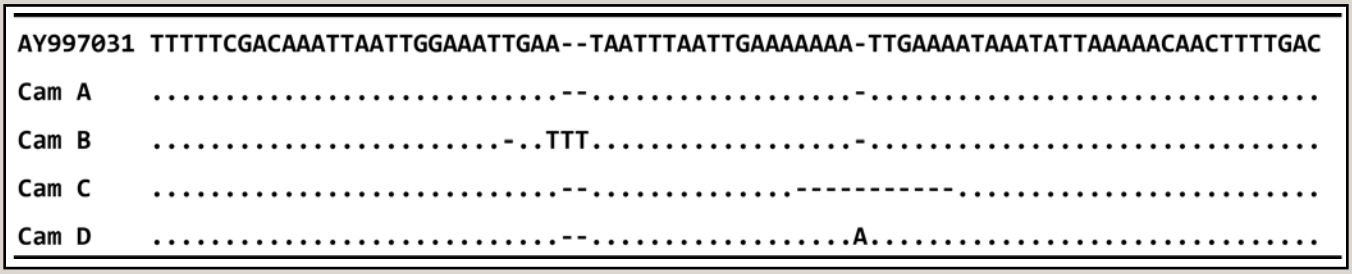

FIG. 2. Alignment of partial sequences of *Bd* isolate AFTOL-ID 21 (AY997031) and haplotypes Cam A to D, retrieved from frogs collected from different locations in Cambodia. The alignment covers bases 41 to 120 of the sequences (297 bp for *Bd* isolate AFTOL-ID 21 (AY997031), including primer sequences Bd1a and Bd2a), indicating only the differences in sequences among haplotypes CAM A to D and to *Bd* isolate AFTOL-ID 21 (James et al. 2006).

prevalence of infection of 35% (i.e., 27 of 77 individuals). A similar infection rate was obtained for Kratie (23 of 66 individuals) where 7 species were sampled and individuals of 5 species were found to be positive for *Bd*. A lower infection rate of 22% (14 of 65 individuals in 6 of 12 species) was obtained at ACCB, while market frogs all belonging to the species *Hoplobatrachus rugulosus* showed the highest prevalence of infection with 73% (22 of 30 individuals) (Table 1). These results demonstrate the presence of *Bd* in amphibians from different parts of Cambodia, revealing a similar detection prevalence compared to our previous study on amphibians from the southwestern part of Cambodia, including isolated areas in the Cardamom Mountains (Mendoza et al. 2011). The high prevalence of *Bd* in market frogs also confirms the previously reported trend of higher detection rates of *Bd*-infected amphibians in man-made environments such as pet shops or markets (Bai et al. 2010; Goka et al. 2009) which is likely a consequence of increased potential for cross-contamination due to the space limitations typically experienced by the large quantities of amphibians present.

TABLE 1. Detection of *Batrachochytrium dendrobatidis* (*Bd*) in frogs collected in Cambodia at Phnom Penh, the Angkor Center for the Conservation of Biodiversity (ACCB), Kratie, and Sihanoukville Market.

All 86 300-bp amplicons obtained in this study were purified, and then sequenced at the DNA Sequencing Facility of the Institute for Cellular and Molecular Biology at the University of Texas at Austin, Texas. Sequences were compared to GenBank/EMBL databases and aligned using BLAST (Pearson and Lipman 1988) and alignment functions in Geneious 4.8.3 (Drummond et al. 2009). Sequence diversity was limited with 4 haplotypes being discovered (Cam A, B, C, and D) (Table 1, Fig. 2). All haplotypes differed from each other by small sequence variation in the same region of the amplicon (Fig. 2). Compared to Cam A, haplotype Cam B differed by a 2-bp insertion and a single nucleotide substitution, while haplotype Cam C was characterized by a 10 bp deletion, and haplotype Cam D by one additional base. All haplotypes were represented by identical sequences of isolates in the GenBank/EMBL databases, except for Cam B where a 1-bp insertion in a different region resulted in only 99.6% similarity to the sequence of an isolate (Bd-08

[AB435218]). The sequence of Cam A was the most encountered in the database with sequences of more than 25 isolates being identical (e.g., AFTOL-ID21 [AY997031] or NE14 [EU779863]), while those of the remaining haplotypes were rare with sequences of 1 or 2 isolates being identical (Bd-04 [AB435214] for Cam C, and MF22879 [FJ232005], and MF22913 [FJ232007] for Cam D).

The prominence of haplotype Cam A in the databases was reflected by its detection frequency in our samples. Cam A was the most abundant haplotype at all locations representing 59-78% of all *Bd*-positive samples (Table 1). It was also present and most abundant on all amphibian species that tested positive for *Bd*. Haplotype Cam A is identical to "haplotype A" discovered in a large survey of *Bd*-infected amphibians in Japan (Goka et al. 2009). Similar to haplotype Cam A in our study, haplotype A was a major contributor to *Bd* infections, both in man-made and in natural systems, with most of the remaining 25 haplotypes B-Z recovered from Japan detected at much lower frequency. The distribution of haplotype A in Japan, however, was not as prominent as Cam A in our study. In Japan, only few species and individuals were infected per location, and large differences in prevalence amongst infected species was observed among locations (Goka et al. 2009). The remaining three haplotypes, Cam B, C, and D, were found in low frequency. Haplotype Cam C was identical to haplotype E identified in Japan, and Cam B was represented by haplotype I (though with one mismatch). For Cam D, however, no representative haplotype was found in that study (Goka et al. 2009). Consequent with their low frequency in detection, it is not surprising that these haplotypes were not present at all locations or for all amphibian species. Patterns of detection with Cam C absent at Phnom Penh, Cam B absent at ACCB and Kratie, and Cam D absent at Sihanoukville market (Table 1) might therefore entirely be due to the low frequency of detection. As this study only provides initial data for chytrid fungus and potential effects within Cambodia, any further statements about the significance of these distribution patterns would thus be highly speculative, and the matter requires additional studies.

Acknowledgments.—The authors are indebted to the Ken and Verena Wilson Foundation, the National Science Foundation (GK-12 grant No. 0742306), the Zoological Parks and Gardens Board of Victoria (Australia), the Darwin Initiative (UK: 14-037, EIDPO028), and the John D. and Catherine D. MacArthur Foundation (US: 09-92411-000-GSS) along with Texas State University–Department of Biology for financial support. We also thank Markus Handschuh and the Angkor Centre for Conservation of Biodiversity (ACCB) as well as Troy Saville and Verne Dove from the World Wildlife Federation for accommodation and support during the fieldwork for this project and the Royal University of Phnom Penh (RUPP) for its contributions to the laboratory work there. Peer review by N. Furey improved the final manuscript. The research was carried out in compliance to the rules overseen by the Texas State Institutional Animal Care and Use Committee (IACUC, permit 0915-0520-14), and within country coordination from Neil Furey, Head of Academic Development at Fauna and Flora International (Cambodia).

Chytrid Fungus in American Bullfrogs (*Lithobates catesbeianus*) along the Platte River, Nebraska, USA

Chytridiomycosis is an emerging infectious disease in amphibians that was discovered in the late 1990s (Berger et al. 1998; Longcore et al. 1999), with retrospective surveys indicating isolated cases dating to 1902 in Japan (Goka et al. 2009), 1938 in Africa (Weldon et al. 2004), and 1961 in North America (Ouellet et al. 2005). This disease is caused by the pathogen *Batrachochytrium dendrobatidis* (*Bd*), a species of chytrid fungus, and it is hypothesized to contribute to amphibian declines worldwide (Berger et al. 1998; Daszak et al. 1999; Lips et al. 2006; Collins 2010). *Bd* has been detected in amphibians on all six continents inhabited by amphibians, and large numbers of *Bd*-positive samples have been collected from various sites across North America (www.Bd-maps.net; accessed 7 June 2011). The central United States, however, has not been sampled extensively for *Bd*. To date, no published accounts of *Bd* exist for amphibians from Nebraska, USA, although two localities with *Bd* in Nebraska are noted online (www.Bd-maps.net; J. Krebs, Henry Doorly Zoo, Omaha, Nebraska, and Zimmerman Ranch, Dunning, Nebraska). Our objective was to determine whether *Bd* is present along the Platte River in south-central Nebraska.

We sampled anurans along the Platte River in Hall County, Nebraska, on land managed by Platte River Whooping Crane Critical Habitat Maintenance Trust, Inc., located on Shoemaker Island (40.7884°N, 98.4650°W). We prioritized capturing *Lithobates catesbeianus* (American Bullfrog) because they are nonclinical carriers of *Bd* (Daszak et al. 2004; Garner et al. 2006), are abundant in Nebraska (Fogell 2010), and are a concern for wildlife management worldwide due to their invasiveness (Ficetola et al. 2007). We targeted sampling along two sloughs (linear, water-filled depressions) surrounded by mesic, tall-grass prairie (Fig. 1; Slough 1 start: 40.7921°N, 98.4628°W; end: 40.7939°N, 98.4584°W; Slough 2: start: 40.7959°N, 98.4444°W, end: 40.7989°N, 98.4421°W). We also opportunistically collected *Anaxyrus woodhousii* (Woodhouse's Toad) and *Lithobates blairi* (Plains Leopard Frog) from these sloughs, as well as nearby point locations across the island, including isolated ponds, puddles, and roads (Fig. 1). Samples were collected 28 April, 5 June, 9 and 10 July, and 3 and 6 September 2010.

To minimize contamination, we captured amphibians by hand while wearing disposable vinyl gloves that we changed between each capture. We also captured some Plains Leopard Frogs with nets from ponds and puddles. Each animal captured was kept individually in plastic or cloth bags until processed in the field and then released; plastic bags were disposed after one usage whereas cloth bags were washed between samples. For each individual, we determined sex and visually examined for wounds and other abnormalities. We sampled for *Bd* following protocols of the Amphibian Disease Laboratory, Institute for Conservation Research at the San Diego Zoo and used their preferred sampling kits, comprised of plastic-handled, fine tip cotton swabs (Dryswab™; MW113; Medical Wire & Equipment Co. LTD., England) and screw-top storage tubes (Cryogenic Vials, Nalge Nunc International, New York). We swabbed the skin on ventral surfaces, targeting the pelvic patch, thighs, and toe webbing, making 5 passes on each surface with a single swab for each animal. The swab was air-dried, and the tip placed in an individually marked vial.

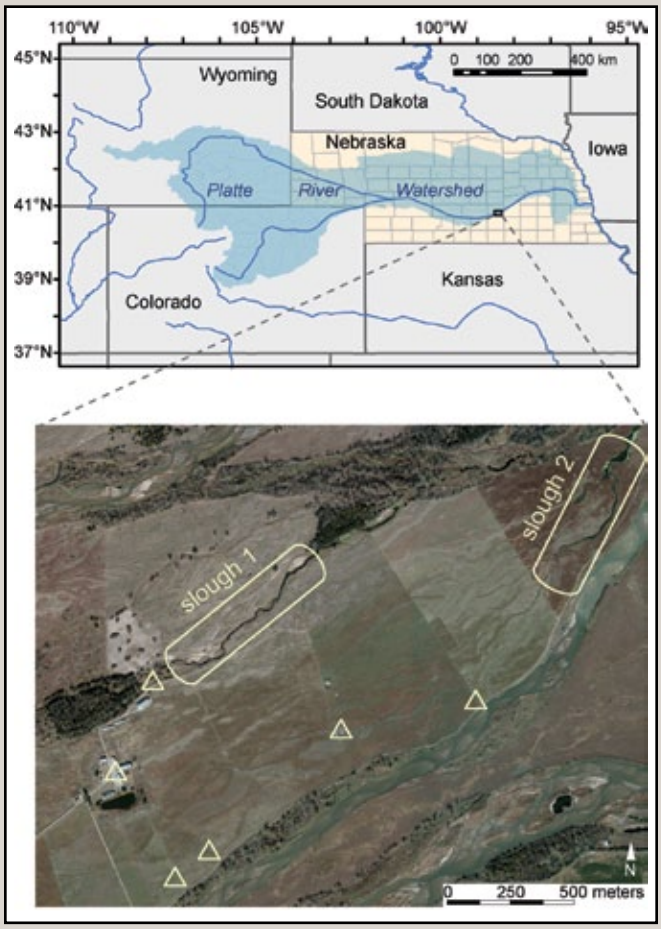

FIG. 1. Location of sampling sites along the Platte River in central Nebraska, USA. Locator map shows the study region within the Platte River watershed. Aerial photograph depicts Shoemaker Island (Hall County, Nebraska) where anurans were sampled. Most sampling occurred in sloughs 1 and 2, and opportunistic captures were collected from point locations (denoted by triangles). Aerial photograph was taken in October 2010.

Samples were shipped to the San Diego Zoo for processing where they were analyzed for *Bd* using real-time (Taqman) PCR to amplify the ITS1 region (Boyle et al. 2004). Results were reported as positive or negative. We examined associations among *Bd* presence, sex, sampling date, and sampling location with Pearson Chi-square tests in PASW Statistics version 18 (Chicago, Illinois, USA).

We captured a total of 118 amphibians, including 76 adult American Bullfrogs, 1 American Bullfrog tadpole, 20 Plains Leopard Frogs, and 21 Woodhouse's Toads. We detected *Bd* only in American Bullfrogs, with 31 adults (41%) testing positive. We did not detect an association between *Bd* infection and sex (χ^2 = 1.14, df = 1, P = 0.28) or sampling location (χ^2 = 1.81, df = 2, P = 0.40), but we found an association between *Bd* infection and sampling date (χ^2 = 14.12, df = 2, P = 0.001), with 67% of American Bullfrogs testing positive in April, 0% testing positive in June, and 39% testing positive in July. We observed infected American Bullfrogs in both sloughs; the one American Bullfrog sampled from an isolated pond located 600 m from the sloughs tested negative. No infected individuals were detected in the other two species, even in sloughs with infected American Bullfrogs (N = 2 Woodhouse's Toads collected from Slough 1, N = 18 Plains Leopard Frogs collected from Slough 1, and N = 1 Plains Leopard Frog from Slough 2).

We detected high prevalence of *Bd* (41%) in American Bullfrogs along the Platte River in central Nebraska. Other central USA accounts of *Bd* include surveys in the north-central United States (Iowa, Wisconsin, and Michigan), where *Bd* was detected in nine species, including American Bullfrogs (Sadinski et al. 2010); surveys in Colorado and Wyoming, where *Bd* was widely distributed (51% of sites examined) in Boreal Toads (*Bufo boreas boreas*), Western Chorus Frogs (*Pseudacris triseriata*), Northern Leopard Frogs (*Lithobates pipiens*), and Wood Frogs (*Lithobates sylvaticus*) (Young et al. 2007); and surveys along the Rocky Mountains, where *Bd* was detected in six species (Muths et al. 2008). Additional surveys of *Bd* throughout the central United States are warranted to gain baseline information about the presence of this pathogen, especially as it relates to species that have declined in recent decades for unknown reasons (e.g., Hayes and Jennings 1986).

Accumulating evidence supports the "novel pathogen hypothesis" to explain the recent worldwide invasion of *Bd* (Rosenblum et al. 2009). This specifically suggests that human-mediated movement of infected frogs, including the American Bullfrog, precipitated *Bd* range expansion (Fisher and Garner 2007; Schloegel et al. 2009a,b). In light of this, our results are a special concern for the region as American Bullfrogs were introduced to waterways throughout Nebraska in the 20th century and appear to be expanding their distribution (Fogell 2010). American Bullfrogs were not documented in surveys of herpetofauna in 1980 on an island adjacent to our study site (Jones et al. 1981), but they were abundant in our 2010 surveys. Expansion of American Bullfrogs could result in the introduction of *Bd* to the native amphibians in the region, notably Plains Leopard Frogs, Woodhouse's Toads, and Boreal Chorus Frogs. *Bd* infections already have been reported in Chorus Frogs (*Pseudacris maculata* and *P. triseriata*) and Northern Leopard Frogs (*Lithobates pipiens*) in Colorado and Wyoming (Young et al. 2007; Muths et al. 2008). Although we did not detect *Bd* in Plains Leopard Frogs or Woodhouse's Toads, a number of factors may have prevented this. Our sample size was small (Skerratt et al. 2008), and studies have shown lower prevalence of *Bd* during the summer (Longcore et al. 2007; Retallick et al. 2004; Voordouw et al. 2010). In our study, most positive detections of *Bd* were at the earliest sampling date (April) in American Bullfrogs, but we captured most Plains Leopard Frogs and Woodhouse's Toads at later sampling dates, thus we may have missed a seasonal peak in infection. In addition, recent work suggests that our collection method (swabbing) is less sensitive than other methods (toe clips and bag rinses) for detection (Voordouw et al. 2010).

Additional surveys of native anurans need to be conducted at this site to monitor potential cascading effects of transmission of *Bd* from invasive American Bullfrogs. Prevalence of *Bd* varies among American Bullfrog populations, but it is frequently high (Garner et al. 2006), and American Bullfrogs are often nonclinical carriers (Daszak et al. 2004; Garner et al. 2006). Despite high genetic similarity of isolates, different strains of *Bd* differ in virulence (Berger et al. 2005; Fisher et al. 2009; Rosenblum et al. 2009), yet there appears to be little host specificity (James et al. 2009; Rosenblum et al. 2009). Thus, *Bd* strains carried by American Bullfrogs likely are easily spread to other native species. Therefore, characterization of the strain of *Bd* in this region is needed because American Bullfrogs occur in the same water bodies with many native species and may threaten them, especially if carrying a lethal strain.

Acknowledgments.—We thank the Wildlife Disease Laboratories at the San Diego Zoo for analyzing samples. For assistance with field sampling, we thank Lauren Gomez and Chelsey Batenhorst, as well as visiting students from the Autonomous University of Nuevo León: Jonathan Marroquin Castillo, Gilberto Rodríguez, Oscar Oswaldo Rodríguez, Homero Alejandro Gárate Escamilla, Andrés Solorio Pulido, Francisco Vallejo Aguirre, José Ignacio Galván Moreno, and Indira Reta Heredia. Funding was provided by the Nebraska State Wildlife Grants Program (Nebraska Game and Parks Commission and U.S. Fish & Wildlife Service), University of Nebraska at Kearney (UNK) Undergraduate Research Fellows Program, and Pepsi Experiential Learning Program. Research was approved by the UNK Institutional Animal Care and Use Committee (IACUC #062409), and individuals were studied under authorization of the Nebraska Game and Parks Commission (Scientific and Educational Permit No. 1031 issued to Keith Geluso).

Batrachochytrium dendrobatidis in *Plectrohyla arborescandens* (Anura: Hylidae) Larvae at a Montane Site in the Sierra Negra, Puebla, México

The amphibian chytrid fungus *Batrachochytrium dendrobatidis* (*Bd*) has been detected on all continents where amphibians occur (Berger et al. 1998; Bosch et al. 2001; Fisher et al. 2009; Hopkins and Channing 2003; www.Bd-maps.net, accessed 7 June 2011), causing a widespread cutaneous infection in young postmetamorphic and adult individuals that may result in death (Berger et al. 1999). Although anuran larvae do not seem to die from the infection, they nonetheless develop remarkable damage to their keratinized mouthparts (interrupted or misshaped tooth rows, and loss of pigmentation in these and jaw sheaths) and swelling and redness of the labial papillae and oral disc (Berger et al. 1998; Fellers et al. 2001).

During a field survey in June 1996, one of us (LCM) collected *Plectrohyla arborescandens* tadpoles in a stream in Zoquitlán, southeastern Puebla, México (18.3239°N, 97.01°W; 1860 m elev.), a geographic region known as the Sierra Negra (Fig. 1). Seven of 13 (54%) larvae lacked jaw sheaths and tooth rows (L. Canseco-Márquez, pers. obs.; specimens are retained at the herpetological collection of Benemérita Universidad Autónoma de Puebla, México; EBUAP 681–682). At that time, *Bd* was not yet described, its effects were yet unknown, and the cause of the missing jaw sheaths and tooth rows in larvae was not clear to the surveyors. Based on those original observations and more recent information regarding the existence and effects of *Bd*, our aim was to return to the region and sample *P. arborescandens* larvae for the presence of *Bd*.

Our study was conducted in Tilancingo, a stream located in the municipality of Coyomeapan, Puebla, Mexico (in the Sierra Negra; 18.3027°N, 97.0644° W; 2607 m elev., Fig. 1), where the vegetation (oak-pine forest) is relatively undisturbed. In June 2008, we collected four tadpoles (EBUAP 2114) of *P. arborescandens*, and took them to the laboratory to test for the presence of *Bd* using the wet-preparation technique (Frías-Alvarez et al. 2008). We also examined another 22 larval *P. arborescandens* (EBUAP 2109-13) for mouthpart abnormalities that were collected at the same site in March–June 2006.

To characterize the oral disc abnormalities in larvae, we examined mouthparts with a stereoscopic microscope. Individuals at Gosner stages 40–42 (Gosner 1960) were excluded from the analysis because during these stages atrophy of the oral disc is a natural process (Gosner 1960).

The four tadpoles collected in 2008 (stages 26–37) were infected with *Bd*, which was determined by the presence of empty sporangia, sporangia with zoospores and septed sporangia. Further, these four tadpoles also had conspicuous oral disc abnormalities; loss of the jaw sheaths and tooth rows (with anterior and posterior mouthparts being affected in both cases). Of the specimens examined from 2006, 18 of 22 larvae (stages 26–35) had oral disc abnormalities. In total, the incidence of mouthpart abnormalities was 84.6% (N = 26).

The presence of *Bd* in Puebla State recently was documented by Frías-Alvarez et al. (2008) in *Ambystoma velasci*, so this represents the second report of the fungus in Puebla, and the first case associated with an anuran species. *Bd* occurrence in *P. arborescandens* is of particular concern because this is an anuran with conservation concerns. This frog is endemic to the Atlantic slopes of México, in the states of Tlaxcala, Puebla, and Veracruz, and is considered endangered and with a decreasing population trend (Stuart et al. 2008).

It warrants acknowledgment that other factors aside from *Bd* infection can cause loss of the keratinized mouthparts in anuran larvae. These include low temperatures, possibly related to decreased feeding (Rachowicz 2002), and DDT and corticosterone exposure (Hayes et al. 1997). However, the *Bd* pattern of loss presents differently. Whereas tadpoles infected with *Bd* show loss of jaw sheaths in form of 'gaps' (whitish areas on the jaw sheaths that are discontinuous, surrounded by darkened areas), those exposed to low temperatures experience a continuous reduction in tooth rows, and later in jaw sheath width (Rachowicz and Vredenburg 2004). On the other hand, tadpoles exposed to DDT and corticosterone lose the anterior jaw sheaths and tooth rows completely, with no posterior mouthparts being affected (Hayes et al. 1997). In our samples both anterior and posterior mouthparts were affected, about equally, and whitish gaps irregularly distributed in the jaw sheaths and tooth rows were found, which resembles the pattern described for tadpoles infected with *Bd* (Rachowicz and Vredenburg 2004). Additionally, although DDT or corticosterone may occur at the site (e.g., via aerial transmission), the area is surrounded by primary vegetation and direct applications of the chemicals are unknown. Moreover, tadpoles were collected in some of the warmest months, which reduces the possibility of mouthpart loss due to low temperatures. Based on these observations, we suggest that the fungus was the most likely proximate cause of the abnormalities reported herein.

The larvae we collected appeared healthy, as did the adults of *P. arborescandens* that we found (none dying or dead). However, the incidence of abnormalities in larvae was as high as other reports for anuran species inhabiting montane regions (Felger et al. 2007; Fellers et al. 2001; Lips et al. 2004), unlike lowland sites, where incidence is lower (Felger et al. 2007). This is consistent with reports on the prevalence of chytridiomycosis and *Bd* related declines; prevalence increases with altitude (Woodhams and Alford 2005), and declines due to the disease occur mainly

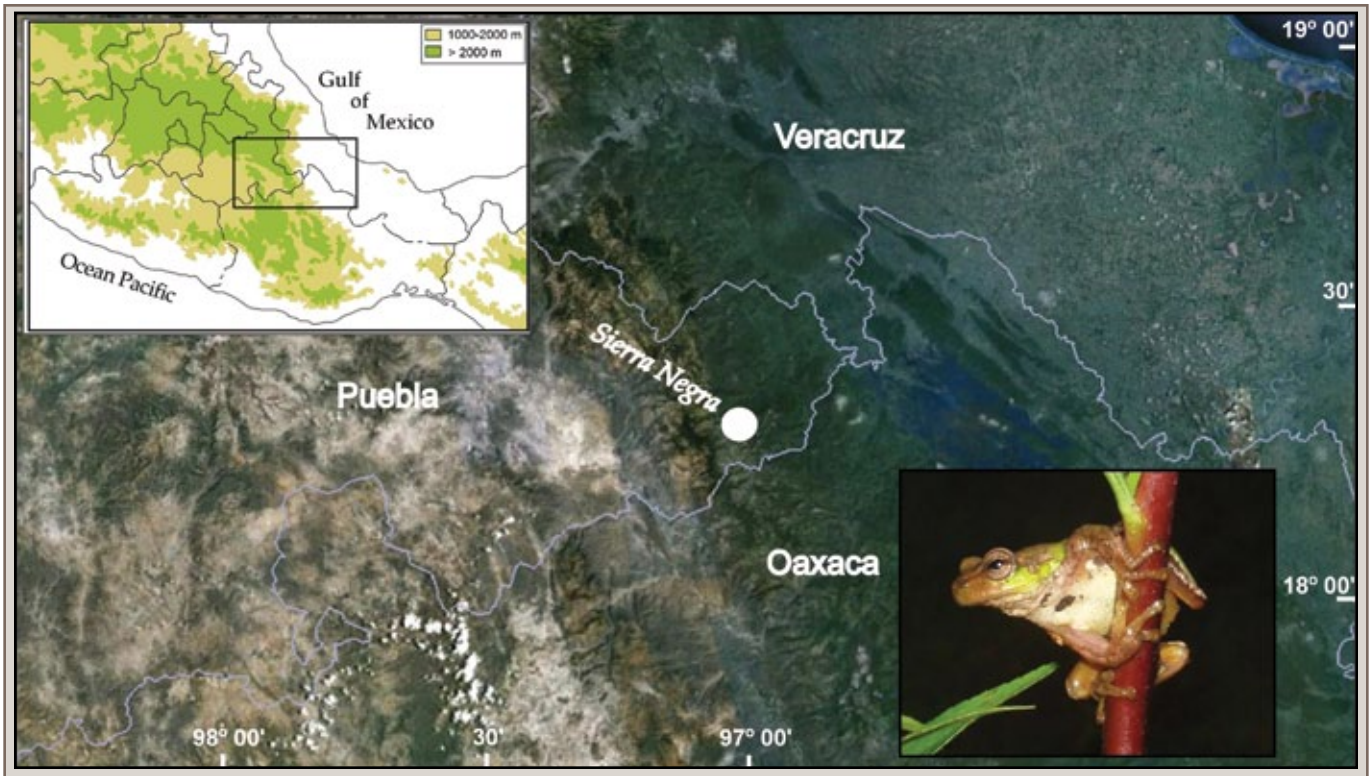

FIG. 1. Map of southeastern Puebla and adjacent states in México, showing the location of the Sierra Negra. White circle indicates Tilancingo stream, the area where *Batrachochytrium dendrobatidis* was detected on *Plectrohyla arborescandens* larvae. Also shown is an adult male *P. arborescandens* from this locality.

at montane sites (Berger et al. 1998; Lips 1999). *Bd* growth is favored at relatively cool environmental conditions, so this might explain the patterns described above (Daszak et al. 2003). Additionally, other factors, such as specific susceptibility to the fungus, length of larval period, and behavior of the tadpoles, might have an effect on the incidence of abnormalities in this life stage.

Because montane sites form a great proportion of the Sierra Negra, and many of its amphibian species are endemic to México (e.g., *Plectrohyla arborescandens, P. bistincta, Hyla euphorbiacea, Craugastor mexicanus*, and *Incilius occidentalis*) and some are endemic to this montane location in Puebla State (e.g., *Craugastor galacticorhinus* Canseco-Márquez and Smith 2004), studies are needed to evaluate the current distribution of *Bd* in the entire region, which species are affected, as well as its effects at both the individual and population level.

Infectious Disease Screening of *Indirana* Frogs from the Western Ghats Biodiversity Hotspot

Amphibians are undergoing global declines, with 41% of amphibian species threatened with extinction (Hoffmann et al. 2010; Stuart et al. 2004). Emerging infectious diseases such as chytridiomycosis and *Ranavirus* have been implicated among the possible reasons for some of these declines (e.g., Collins and Storfer 2003; Daszak et al. 1999; Schloegel et al. 2010). Chytridiomycosis is a disease caused by the parasitic fungus *Batrachochytrium dendrobatidis* (*Bd*). It is known to cause mortality across a wide range of amphibian taxa by the disruption of cutaneous functions (Voyles et al. 2009). *Bd* infections were first reported in Panama and Australia in 1998, and are now known to affect amphibians across the globe, including species in North America, South America, Central America, Africa, Europe, New Zealand, and in parts of Asia (e.g., Berger et al.1998; Bradley et al. 2002; Changming et al. 2010; Garner et al. 2005; Kielgast et al. 2010; Lips 1999; Waldman et al. 2001). The viral amphibian pathogen *Ranavirus*, which is less well reported, also causes mass mortalities in the wild (Gray et al. 2009), in both common amphibian species and species thought to be in decline (e.g., Green et al. 2002). For example, it is known to cause mass mortalities in Eastern Tiger Salamanders (*Ambystoma tigrinum*) in North America (Bollinger et al. 1999; Collins et al. 2004; Jancovich et al. 1997) and in the Common Frog (*Rana temporaria*) in the United Kingdom (Cunningham et al. 1996). Furthermore, recent studies have shown that *Ranavirus* infection can cause long-term population declines in *R. temporaria* (Teacher et al. 2010).

To the best of our knowledge, no screening for *Bd* or *Ranavirus* has been reported from the Indian sub-continent, representing a very large gap in our knowledge of the distribution of these diseases. This is also evident from the current global distribution map of *Bd* (www.bd-maps.net; accessed 2 May 2011).

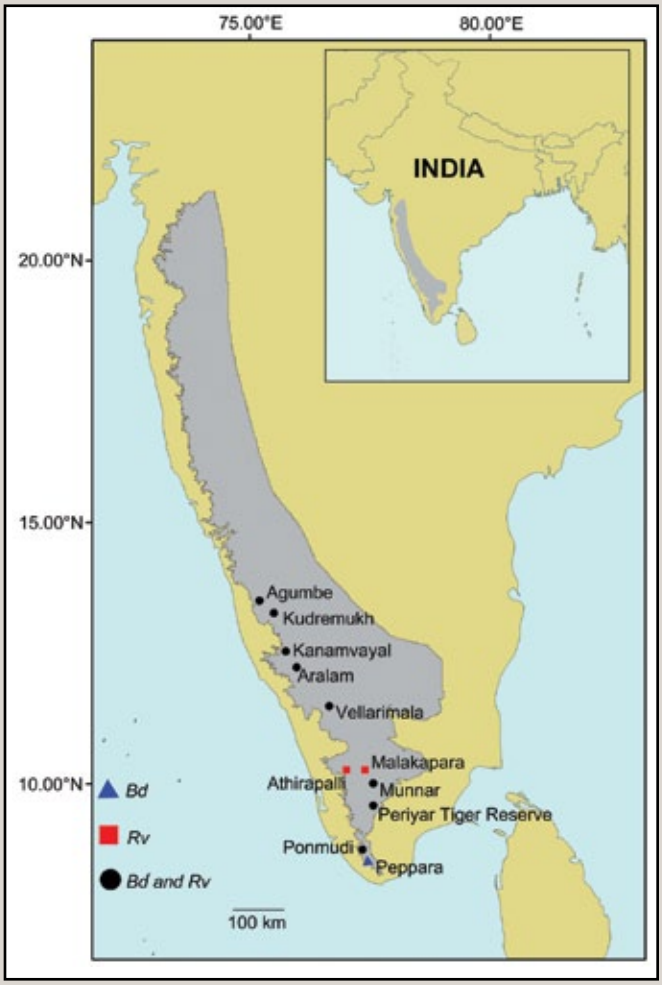

Fig. 1. Locations of the sites in India screened for *Batrachochytrium dendrobatidis* (*Bd*) and *Ranavirus* (*Rv*).

The Western Ghats in southwestern India is a biodiversity hotspot (Myers et al. 2000) which has a high diversity of amphibians with many endemic families and genera (Biju and Bossuyt 2003; Bossuyt et al. 2004; Daniels 2005; Dutta 1997). Currently, there are approximately 132 known amphibian species that are unique to the Western Ghats (Dinesh et al. 2009). We investigated the presence of *Bd* and *Ranavirus* in several species of *Indirana* frogs endemic to the Western Ghats biodiversity hotspot. In addition, *Bd* screening was performed for *Hylarana temporalis*, *Fejervarya keralensis*, and *Micrixalus fuscus* from the Peppara Wildlife sanctuary in Kerala, India.

Field surveys were conducted in the southern part of the Western Ghats between 2008–2010, including the states of Kerala and southern Karnataka (Fig. 1). Specimens were identified using published taxonomic information (Daniels 2005; Inger et al. 1984). For the *Ranavirus* screening, 138 samples were collected from 10 locations, including five known and one unknown species within the genus *Indirana* (Table 1). *Indirana beddomii*, *I. semipalmata*, *I. diplosticta*, and *I. brachytarsus* were collected from heavily littered trek paths in tropical evergreen and semi evergreen forests in Peppara, Ponmudi, Malakapara, and the Periyar Tiger Reserve. *Indirana beddomii* frogs were also collected along streams in low altitude sholas in Kudremukh National Park and Agumbe rainforest, as well as from trek paths in moist deciduous forests in Kanamvayal and Aralam. *Indirana leptodactyla* were collected along streams in shola forests in Munnar, and *Indirana* frogs of unknown species (*Indirana* sp.) were collected in semi-evergreen forests in Vellarimala. Toe clips (N = 68 for *I. beddomii*, N = 22 for *I. brachytarsus*, N = 24 for *I. leptodactyla*, N = 5 for *I. semipalmata*, N = 3 for *I. diplosticta*, N = 16 for *Indirana* sp.) were taken from adult specimens and stored in 95% alcohol. Swabs for *Bd* screening were taken from four species of frogs (N = 41 for *I. brachytarsus*, N = 20 for *M. fuscus*, N = 51 for *H. temporalis and* N = 30 for *F. keralensis*) from Peppara Wildlife Sanctuary. All specimens were caught using dip-nets and placed temporarily in separate plastic bags with ventilation. Latex gloves were used and changed every time a new specimen was handled in order to avoid cross contamination among individuals. All frogs were released at the site of capture after collecting the toe-clips and swabs. No physical abnormalities were detected, and there were no indications of unusual mortalities in any of the regions sampled.

For *Ranavirus* screening, total genomic DNA was extracted from the toe clips following the protocol used in St-Amour and Lesbarrères (2007), using the Qiagen DNeasy Blood and Tissue kit (Qiagen, New Delhi, India), following the manufacturer's instructions. DNA isolated from the infected cells of two *Ranavirus* isolates (one from *Bufo bufo*, and one from *R. temporaria*, obtained from the Institute of Zoology, London, UK) were used as positive controls. PCR amplifications were performed twice for each sample using FV3-specific primers (forward: 5'-GTCTCTGGAGAAGAAGAA-3', reverse: 5'-GACTTGGCACTTATGAC-3') which amplify a 420 base pair fragment of the major capsid protein (Gantress et al. 2003; Mao et al. 1996). The PCR amplifications were performed in 15 µl reactions consisting of 3 µl of 5x PCR buffer, 0.12 µl dNTPs (25 mM), 0.5 µl of each primer, 0.15 µl of Phire hot start DNA polymerase (Finnzymes, Finland), 9.23 µl of dH_2O and 1.5 µl of template DNA (10-20 ng). The following thermo cycling conditions were used for amplifications: 98°C for 30 s, followed by 40 cycles of 98°C for 5 s, annealing at 60°C for 15 s, extension at 72°C for 20 s, followed by a final extension step at 72°C for 1 min. The final PCR products were checked on 2% agarose gels, and a sample was considered positive if both the repeat PCR samples showed bands that matched the size of the band (420 base pairs) from the two positive controls.

For *Bd* screening, DNA was extracted from the swabs using a bead beating extraction method with 0.5 mm silica microbeads following the protocol described in Boyle et al. (2004). Some of the toe clip extractions also were screened for *Bd* (Table 1) following methods in Changming et al. (2010). The PCR amplifications were performed in 25 µl reactions using primers ITS-1 (forward): 5'-CCTTGATATAATACAGTGTGCCATATGTC-3' and 5.8S (reverse): 5'-AGCCAAGAGATCCGTTGTCAAA-3' (Boyle et al. 2004). Quantitative Real Time PCR (qPCR) was performed using a Taqman

assay following Boyle et al. (2004) on a 7300 Real Time PCR system (Applied Biosystems, California). We used *Bd* zoospore genome equivalents of 100, 10, 1, and 0.1 to construct the standard curves. All the samples were replicated twice with negative controls on each plate. The genomic equivalents (GE) of the positive samples were derived from the standard curves. A GE score of above 0.1 in each replicate was considered as a positive signal of *Bd* presence. Samples that tested positive in one or both of the replicates were re-tested at Imperial College, London, by an independent researcher in order to confirm the *Bd* infection.

All 138 samples tested for the *Ranavirus* infections were negative: no bands matching the positive control bands were detected (Table 1). Although toe clip extractions have shown to be a good alternative to lethal sampling methods (liver extracts) for the screening of *Ranavirus* (St-Amour and Lesbarrères 2007), the possibility of false negatives cannot be excluded as St-Amour and Lesbarrères (2007) had only 88% success rate in detecting *Ranavirus* from known positive toe-clip extracts.

The 142 samples (DNA extracted from swabs) that were screened for *Bd* infection from Peppara Wildlife Sanctuary were negative for *Bd* infection. From the additional samples that were tested (toe clip extracts), one sample tested *Bd*-positive from *I. diplosticta*, but the replicate was negative for this sample. Another sample of *I. brachytarsus* tested *Bd*-positive and was also positive in the replicate (mean GE = 2.92). These two samples were again amplified with replicates, and tested at Imperial College, London. The *I. diplosticta* sample was found to be negative in both the replicates, and the *I. brachytarsus* sample was positive in both the replicates (Table 1).

From Asia, chytridiomycosis was first reported from captive amphibians in Japan (Une et al. 2008), and *Bd* infections have been reported subsequently from China, Indonesia, and South Korea (e.g., Changming et al. 2010; Kusrini et al. 2008; Yang et al. 2009). To date, we are not aware of any study that has screened for *Bd* or *Ranavirus* in India. In our study, we found one *Bd*-positive *I. brachytarsus* sample from Ponmudi, Western Ghats. The qPCR method is a very specific and sensitive technique for detecting *Bd* infection (Boyle et al. 2004; Kriger et al. 2006), although the infection detected in our study was at a very low level, it was replicable. Rowley et al. (2007) highlighted potential problems associated with contamination due to possible aerosolization of DNA. We believe that aerosol contamination is unlikely in our case, as we performed negative controls and replicated the positive result in a separate laboratory. Similar low-level infections of *Bd* (≤ 1 zoospore equivalent) in wild populations of native amphibians also have been reported from Indonesia and China (Changming et al. 2010; Kusrini et al. 2008). The occurrence of *Bd* infection in individuals with no apparent physical abnormalities is not unusual (e.g., Changming et al. 2010; Kielgast et al. 2010).

Amphibian trade and introductions are prominent hypotheses for the spread of *Bd* in many parts of the world (Fisher and Garner 2007). For example, the introduction of the North American Bullfrog (*Lithobates catesbeianus*) for trade and human consumption is likely to have contributed to the spread of *Bd* in Asia (Changming et al. 2010; Garner et al. 2006). China and Indonesia are well known for amphibian farming and the export of amphibians to Europe, the United States, and many regions in Asia (Kusrini and Alford 2006; Warkentin et al. 2009). Such exports could have facilitated the spread of *Bd* to other regions in southeast Asia. Amphibian trade in India has been banned since 1987 (Warkentin et al. 2009) but illegal trade in amphibians cannot be ruled out as a possible route for introduction of *Bd* to India. A recent study by Goka et al. (2009) also reported the presence of endemic strains of *Bd* in Japanese giant salamander, *Andrias japonicus*, with no disease symptoms. These strains were also present in stored specimens of *A. japonicus* collected in 1902 (Goka et al. 2009), suggesting a much wider and ancient presence of *Bd* in southeast Asia than was previously believed.

Chytrid infections are implicated to have caused extinctions of several species in central Panama even before the scientific description of the species in question were complete (Crawford et al. 2010). The Western Ghats mountains have high endemic amphibian diversity and several new amphibian species have recently been described from this area (e.g., Biju and Bossuyt 2009). Hence, it is highly likely that further new species will be described from this region in future (Biju 2001). In view of our results, and in consideration of the fact that 40% of the amphibian species in the Western Ghats are already threatened with extinction (Biju et al. 2008), we suggest that more organized and extended efforts need to be put into the screening of emerging infectious diseases of amphibians from the entire range of the Western Ghats biodiversity hotspot, and throughout India.

Acknowledgments.—We thank T. Garner for his advice, and for making the facilities and expertise of Institute of Zoology, London available for this study. We thank M. Perkins for help with the laboratory work, and S. Price for the donation of *Ranavirus* control samples. We would also like to thank the Kerala and Karnataka Forest Departments for permission to collect the samples, and B. S. Nair and J. S. Sudharma for help with the field work. The samples were collected under a licence from the National Biodiversity Authority, India (NBA/TECH Appl/9/85/34/08/08-09/682). Our research was funded by the Academy of Finland (grant 125092 and 134728 to JM, and grant 138043 to AGFT) and the Department of Biotechnology, Government of India (grant BT/IN/Finnish/11/SG/2008 to SG).

Batrachochytrium dendrobatidis Detected in Amphibians of the Central Andean Cordillera of Colombia

Land use change, overexploitation, introduced species, global warming, pollution, and emerging infectious diseases are all proposed as causes of the world-wide decline and extinction of amphibians (Alford and Richards 1999; Blaustein and Kiesecker 2002; Collins and Storfer 2003; Fisher et al. 2009). In Latin America, the decline of amphibian populations has been observed from sea level (30 m) to the snow line (5300 m) (Díaz et al. 2007; Puschendorf et al. 2006; Seimon et al. 2007; Whitfield et al. 2007). The emergence of the fungal pathogen *Batrachochytrium dendrobatidis* (*Bd*) has been implicated in several of these declines (Cheng et al. 2011), and it is responsible for the extinction of several species worldwide (Fisher et al. 2009; Skerratt et al. 2007; Lips et al. 2006). In Colombia, *Bd* has been found infecting frogs in the Hylidae, Dendrobatidae, Leptodactylidae, Centrolenidae, and Bufonidae based on histological examination of museum specimens collected in the Eastern and Western Cordilleras (Ruiz and Rueda-Almonacid 2008; Velásquez-E et al. 2008). Here we report the occurrence of *Bd* in amphibians sampled in montane wet forests of the Central Cordillera of Colombia. To the best of our knowledge, this report corresponds to the first and northernmost record for *Bd* for the Central Andean Cordillera in Colombia.

Our field survey was conducted in Belmira, Antioquia, a region located in northwestern Colombia (Fig. 1). This region has an area of approximately 279 km^2, and is mainly covered by pastures and agricultural fields (60%), forests (18%), and shrub/paramo vegetation (21%) (Rodriguez et al. 2007). The forests in the region have been heavily disturbed by mining, cattle grazing, and forest clearance for timber or fuel wood (Corantioquia 2005). Four sites in the region were sampled (Fig. 1), located between 2550 and 2853 m elevation. The region has a bimodal precipitation regime with annual precipitation ranging from 2000 to 2500 mm, with peaks during the months of April–May and October–November (IGAC and IDEA 2007). The sampling sites are classified in the lower montane wet-forest life zone (bmh-MB) (Holdridge 1967). Two of the sites surveyed (Golondrinas and Quebradona) are old forest fragments of approximately 12 ha each. The other two sites (Salema and Santa Rita) are second-growth forest patches of approximately 2 ha each.

Amphibian species were sampled via visual encounter surveys between December 2008 and February 2009 (Table 1). In order to detect *Bd*, 111 individuals of five species were swabbed using methods described by Hyatt et al. (2007). Cross contamination was prevented using a new pair of disposable gloves every time that a new individual was handled. All samples were preserved in 70% ethanol and kept at low temperature (3°C) until quantitative PCR analyses were conducted.

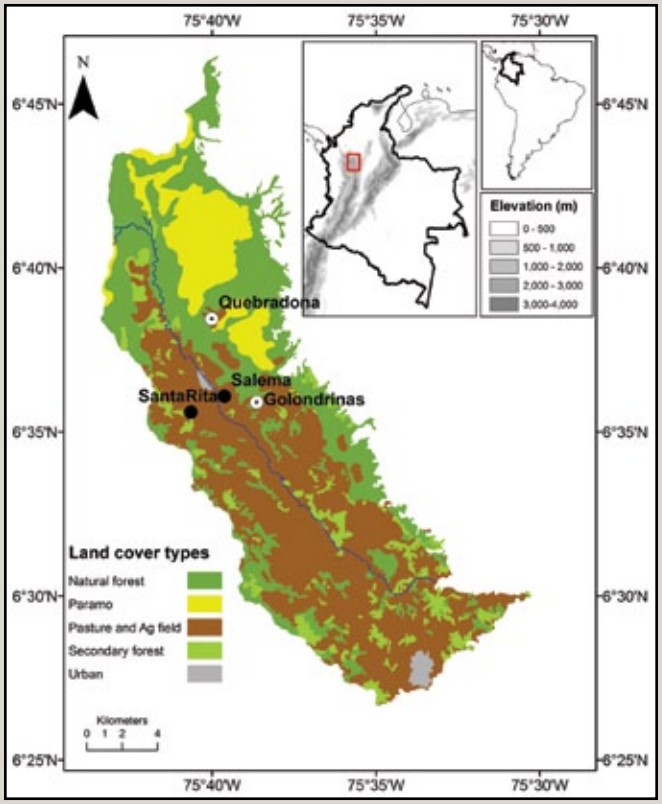

FIG 1. Sampling locations for *Batrachochytrium dendrobatidis* on amphibians in the Central Cordillera, Colombia (South America). White dots = *Bd*-positive locations; Black dots = *Bd*-negative locations.

Bd extraction and quantitative PCR analysis were conducted at the Institute of Zoology, Zoological Society of London, following Boyle et al. (2004). Prevalence of infection was calculated as the ratio between the number of individuals that tested positive for *Bd* and the total number of individuals sampled per species. *Bd* prevalence was estimated with 95% Clopper-Pearson binomial confidence intervals for each species per site. The number of *Bd* zoospores in each swab was estimated as the number of genomic equivalents (GE) per swab by multiplying the number of zoospores detected in each sample by 80, accounting for the number of dilutions between the extraction and the final sample. The number of *Bd* genomic equivalents (GE) is an estimate of the number of zoospores, or the intensity of infection.

We detected *Bd* infection in 32 of 111 amphibians sampled (Prevalence = 28%, CI [95%] = 21–38). However, our low sample

TABLE 1. *Batrachochytrium dendrobatidis* occurrences in amphibians sampled at four sites in Belmira, Antioquia, Colombia. CI = 95% Clopper-Pearson binomial confidence interval for prevalence (%).

Species	Sites (elevation, m)	Coordinates	No. *Bd*-positive / Total no. samples (%)	CI	Mean no. zoospores/ individual (Low, High)
Bolitoglossa ramosi	Golondrinas (2693)	6.5956°N, 75.6406°W	0/10	0–25	0 (0–0)
	Santa Rita (2565)	6.5905°N, 75.674°W	0/45	0–7	0 (0–0)
Pristimantis dorsopictus	Salema (2550)	6.5986°N, 75.6569°W	0/2	0–63	0 (0–0)
Pristimantis piceus	Quebradona (2853)	6.6379°N, 75.6634°W	1/1 (100)	22–100	1263.4 (1263.4–1263.4)
Pristimantis uranobates	Golondrinas (2693)	6.5956°N, 75.6406°W	2/13 (15)	0–43	34.9 (0-389.7)
	Salema (2550)	6.5986°N, 75.6569°W	0/1	22–39	0 (0-0)
Hyloscirtus larinopygion	Quebradona (2853)	6.6379°N, 75.6634°W	29/39 (74)	59–86	459.6 (0–5319.3)

sizes at sites and per species may have precluded *Bd* detection if infection prevalence was low (Skerratt et al. 2008). *Bolitoglossa ramosi,* the only salamander surveyed in this study, was negative for *Bd* at the two sites where the species was found. *Pristimantis dorsopictus* was also negative for *Bd*. At the two second-growth forest sites, no individuals were positive for *Bd* (Table 1). Infected individuals belong to three species (*Hyloscirtus larinopygion*, *Pristimantis uranobates* and *P. piceus*) (Table 1). Intensity of infection ranged between 0 and 5319 zoospores (Table 1). Infected individuals did not show clinical symptoms of the disease.

Hyloscirtus larynopygion had the highest prevalence of the infection (74%), and the highest intensity of infection (Table 1). This high intensity may respond to a larger area of skin sampled in *H. larinopygion* whose size is larger than the other species studied, although we followed a standardized swabbing protocol. This species is listed as IUCN "Near Threatened" (NT), with habitat loss and pollution as the main threats (Bolívar et al. 2008). The absence of historical data on the populations studied here makes it difficult to understand the effects of *Bd* on these populations. However, the high *Bd* prevalence and high intensity of infection documented for *H. larinopygion* in our study suggest that it is imperative to identify whether chytridiomycosis should be considered as a major threat for the species. Monitoring of these populations is needed to better understand their susceptibility to chytridiomycosis. Also, identifying whether other populations in the region are being affected by *Bd* is relevant in order to inform species and land managers. A low number of individuals of *Pristimantis uranobates* and *P. piceus* were positive for *Bd*. These species are listed as "Least Concern" (LC) and although both species are considered adaptable and tolerant to disturbed habitats (Castro et al. 2004), after this study we suggest to consider the presence of *Bd* as one of the causes that can affect their populations even those located in protected areas.

Our study extends the known distribution of the chytrid fungus to the Central Andean Cordillera of Colombia, and to the best of our knowledge, represents the northernmost record for the chytrid fungus for this Cordillera. The results of this study support the hypothesis of habitat loss as a predictor of lower pathogen prevalence (Becker and Zamudio 2011). In our study, all individuals living in second-growth forest sites were negative for *Bd* while the prevalence for individuals from old forests was higher. This may suggest an effect of the structure of the forest on the *Bd* presence even for neighboring populations through changes in microclimatic conditions (Becker and Zamudio 2011), or potentially habitat heterogeneity with reduced pooled water sources that might serve as *Bd* reservoirs. However our modest sample sizes highlight the importance of continued monitoring in the area to include more species and individuals that allow evaluation of this hypothesis. Our new *Bd* report raises conservation concerns considering the high anuran endemism of forests in the northern central Andes (Duellman 1999).

Acknowledgments.—We thank the Corporación Autónoma Regional del Centro de Antioquia (CORANTIOQUIA) and Ministerio de Ambiente y Desarrollo Territorial for providing research and export permits. For logistical support, we thank Grupo Herpetológico de Antioquia (GHA). This research was completed thanks to the support from the Institute of Zoology at the Zoological Society of London, and especially to Trenton Garner for his help and Shane McGuinnes for *Bd* analysis. Finally, we thank Dede Olson and Andrés Merino-Viteri whose comments and suggestions enriched this document.

***NECTURUS MACULOSUS* (Mudpuppy)**. USA: NORTH CAROLINA: Macon Co.: Cullasaja River at Wells Grove, RM 0.9, 3.0 km airline SW Franklin (35.16452911°N, 83.35967785°W; WGS 84). 9 August 2011. Lori Williams, John Groves, David Strickler, Craig Pelke, and Dennis McNamara. Verified by Jeffrey C. Beane. North Carolina State Museum of Natural Sciences photo voucher 12705. First vouchered specimen at this location (North Carolina Natural Heritage Program 2011. Biotics Database. Department of Environment and Natural Resources, Raleigh, North Carolina). Closest previous historical record in North Carolina is from the French Broad River basin, Transylvania County, 60.7 km airline ENE (North Carolina Natural Heritage Program 2011, *op. cit.*). Adult male [TL = 18.5 cm, SVL = 12.0 cm, mass = 20 g] captured while conducting visual encounter surveys. Tissue sample collected. Substantiates an unvouchered record for this drainage obtained during electrofishing surveys in this drainage on 24 July 2000 by Bill McLarney, Cal Yonce, and Will Cobb.

LORI A. WILLIAMS, North Carolina Wildlife Resources Commission, 177 Mountain Laurel Lane, Fletcher, North Carolina 28732, USA (e-mail: lori.williams@ncwildlife.org); **BILL McLARNEY**, Little Tennessee Watershed Association, 93 Church Street, Suite 214, Franklin, North Carolina 28734, USA; **JOHN D. GROVES** and **DAVID STRICKLER**, North Carolina Zoological Park, 4401 Zoo Parkway, Asheboro, North Carolina 27205, USA; **CRAIG PELKE** and **DENNIS McNAMARA**, Virginia Zoological Park, 3500 Granby Street, Norfolk, Virginia 23504, USA.

***PSEUDOTRITON RUBER RUBER* (Northern Red Salamander)**. USA: TENNESSEE: Warren Co.: Hoover Branch of West Fork Hickory Creek, tributary to Caney Fork River. Accessed from Beacon Light Road 0.5 km W of King Road (35.588574°N, 85.912957°W; NAD 27). 6 April 2011. Matthew D. Wagner, Mark S. Hoger, and Andrew S. Riggs. Austin Peay State University Museum of Zoology (APSU 19125, color photo). Verified by A. Floyd Scott. New county record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12, Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp. [Hard copy and Internet versions, the latter of which includes links to information on Tennessee amphibians having appeared since 1996, http://www.apsu.edu/amatlas/, accessed 3 August 2011]). One juvenile caught in seine.

MATTHEW D. WAGNER (e-mail: mwagner5@my.apsu.edu), **MARK S. HOGER**, and **ANDREW S. RIGGS**, Department of Biology, Austin Peay State University, Clarksville, Tennessee 37040, USA.

ANURA — FROGS

***ANAXYRUS AMERICANUS* (American Toad)**. USA: INDIANA: Vigo Co.: Fayette Township: (39.54589°N, 87.42184°W; NAD 83). 10 May 2011. Sarabeth Klueh and Jason Mirtl. Verified by Chris Phillips. Illinois Natural History Survey (INHS 2011m). New county record (Minton 2001. Amphibians and Reptiles of Indiana. 2nd ed., revised. Indiana Academy of Science. vii–404 pp.) Individuals were calling from a flooded agricultural field along with *Anaxyrus fowleri*. This species occurs commonly throughout most of Indiana but appears to be largely absent from a pocket of counties in the southwest part of the state (Minton, *op cit.*). This record partially fills a gap in the range of this species in southwest Indiana.

SARABETH KLUEH (e-mail: sklueh@dnr.in.gov) and **JASON MIRTL**, Wildlife Diversity Section, Indiana Department of Natural Resources Division of Fish and Wildlife, 553 E. Miller Drive, Bloomington, Indiana 47401, USA.

***CHIROMANTIS SIMUS* (Assam Tree Frog)**. BANGLADESH: MOULVIBAZAR DISTRICT: Sreemangol, Lawachara National Park (25.8907694°N, 088.8502083°E, WGS 84), 13 June 2011. Verified by Ghazi S. M. Asmat. Digital voucher image, Herpetology Museum Laboratory, Ichamoti College, Dinajpur, Bangladesh (MHLB-CS01). First record for Moulivibazaar District. Species described from Assam, India (Annandale 1915. Rec. Indian Mus. 11:341–347); first report from Bangladesh was Chittagong (Asmat et al. 2003. Univ. Rajshahi J. Zool. 2003:141–143).

SHAHRIAR CAESAR RAHMAN, Department of Environmental Science, Independent University, Bangladesh (e-mail: caesar_rahman2004@yahoo.com); **M. SAJID ALI HOWLADER**, Department of Zoology, University of Chittagong, Bangladesh (e-mail: sajidpabc@gmail.com).

***DISCOGLOSSUS GALGANOI* (West Iberian Painted Frog)**. PORTUGAL: ÉVORA: ca. 38.5269°N, 08.0168°W (WGS84). 17 November 2011. Luis Ceríaco. Photographic vouchers deposited at Colecção Fotográfica of the Museu de Ciências Naturais da Escola Secundária André de Gouveia (MCN/MB/F/A/10). Verified by Ana Pires. Species previously unrecorded from region, nearest population being at least 10 km S (Cruz and Rebelo 2010. *In* Loureiro et al. [eds.], Atlas dos Anfíbios e Répteis de Portugal, pp. 104–105. Esfera do Caos Editores, Lisboa). Photographed in water canal, in Herdade da Mitra, at ca. 2330 h.

LUIS MIGUEL PIRES CERÍACO, Projecto "Salvem as Osgas!" and Centro de Estudos de História e Filosofia da Ciência, Universidade de Évora, Bairro do Bacelo, Rua do Viveiro nº 5D, 7005–638 Évora, Portugal; e-mail: luisceriaco@netcabo.pt.

***ENGYSTOMOPS PUSTULOSUS* (Túngara Frog, Sapillo Túngara)**. HONDURAS: YORO: 5 km S of San Patricio (15.400000°N, 86.916667°W, WGS84; 250 m elev.). 5 October 2010. James R. McCranie and Leonardo Valdés Orellana. Verified by Steve W. Gotte. USNM 578911. First record for Yoro, with the closest known locality being ca. 35 km SE at El Díctamo, Olancho (McCranie 2006. Smithson. Herpetol. Inform. Serv. 137:1–38). The frog was calling at night in a rain pool on a dirt road in an area of badly degraded thorn forest.

JAMES R. McCRANIE, 10770 SW 164th Street, Miami, Florida 33157–2933, USA (e-mail: jmccrani@bellsouth.net); **LEONARDO VALDÉS ORELLANA**, Gerente General de "Hondufauna," Investigador Privado, Colonia América, Bloque 9, Casa 1806, Comayagüela, MDC, Honduras (e-mail: leovalor@hotmail.com).

***FEJERVARYA ASMATI* (Bangladeshi Cricket Frog)**. BANGLADESH: NILPHAMARI DISTRICT: Darwny Textile Mills, Shokher Bazar (25.890769°N, 88.850208°E; 43–44 m elev.; datum: WGS 84). 13 June 2011. Collected by Md. Abdur Razzaque Sarker. Two specimens (MHLB-FA01, and MHLB-FA02). Museum of Herpetology Laboratory, Ichamati College, Dinajpur, Bangladesh. Verified by Ghazi S. M. Asmat. Species described from Chittagong, Bangladesh (Howlader 2011. Zootaxa 2761:41–50). Current population 1.83 km from Darwny Textile Mills Market and >600 km N of type locality. Adults collected on banks of pond. Habitat includes several *Cynodon dactylon* plantations, in addition to Bambuseae, *Bromus tectorum*, adjacent to a field of *Corchorus capsularis*.

MD. ABDUR RAZZAQUE SARKER (e-mail: razzaqsciencebd@gmail.com), and **MOHAMMAD SAJID ALI HOWLADER** (e-mail: sajidpabc@gmail.com), Herpetology Laboratory, Bangladesh; House number: 28/5 (2nd floor), Shonatangar, Jigatola, Dhanmondi, Dhaka 1209, Bangladesh.

***FEJERVARYA PIERREI* (Pierre's Cricket Frog)**. BANGLADESH: NILPHAMARI DISTRICT: Berakuthi, Barua (25.821925°N, 88.8284°E, 43 m elev.; WGS 84), 29 August 2011. Verified by Ghazi S. M. Asmat. Collected by Md. Abdur Razzaque Sarker. Museum of Herpetology Laboratory, Ichamati College, Dinajpur, Bangladesh (MHLB-FP01). First record from Nilphamari District, northern Bangladesh, and previously recorded from Chittagong (Hathazari), Coxes bazaar (Himchari), Noakhali (Hatia Island), and Barisal (Sundargaon), southeast Bangladesh (Rasel et al. 2007. Bannoprani- Bangladesh Wildl. Bull. 4:1–2). Current population found near a Berakuthi, Barua, a primary school, >14 km S from Nilphamari and > 484 km NW of the Chittagong (Hathazari), < 570 km NW of Cox's Bazaar (Himchari), < 400 km NW of Noakhali (Hatia Island), and < 377 km NW fof Barisal (Sundargaon). Adult collected beside playground. Habitat includes *Cynodon dactylon* plantations, beside paddy field.

MD. ABDUR RAZZAQUE SARKER (e-mail: razzaqsciencebd@gmail.com), **MOHAMMAD SAJID ALI HOWLADER** (e-mail: sajidpabc@gmail.com), Herpetology Laboratory Bangladesh, House no:28/5, 2nd floor, Shonatangar, Jigatola, Dhanmondi, Dhaka 1209, Bangladesh.

***FEJERVARYA TERAIENSIS* (Terai Cricket Frog)**. BANGLADESH: MOULVIBAZAR DISTRICT: Sreemangol, Lawachara National Park (25.8907694°N, 088.8502083°E, WGS 84), 13 June 2011. Verified by Ghazi Asmat. Digital voucher image, Herpetology Museum Laboratory, Ichamoti College, Dinajpur, Bangladesh (MHLB-FT01). First record for Moulivibazaar District. Only reports from Bangladesh is Chittagong, Cox's Bazaar, Barisal, and Nokhali Districts (Rasel et al. 2007. Bannoprani-Bangladesh Wildl. Bull. 4:1–2).

SHAHRIAR CAESAR RAHMAN, Department of Environmental Science, Independent University, Bangladesh (e-mail: caesar_rahman2004@yahoo.com); **M. SAJID ALI HOWLADER**, Department of Zoology, University of Chittagong, Bangladesh (e-mail: sajidpabc@gmail.com).

***HYLA GRATIOSA* (Barking Treefrog)**. USA: TENNESSEE: Benton Co.: 4185 Divider and Natchez Road (35.5943°N, 88.0905°W; NAD 83). 26 April 2011. Brian Elkins. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 19130). First county record (Scott and Redmond 2008. Atlas of Amphibians in Tennessee. Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. http://www.apsu.edu/amatlas [updated 13 October 2010; accessed 12 September 2011].

Voucher image made under the authority of the Tennessee Wildlife Resources Agency; field work supported by State Wildlife Grant (SWG) funding under the authority of the U.S. Fish and Wildlife Service.

ROBERT COLVIN, Tennessee Wildlife Resources Agency, Region I, 200 Lowell Thomas Drive, Jackson, Tennessee 38301, USA; e-mail: Rob.Colvin@tn.gov.

***HYLARANA LEPTOGLOSSA* (Long-tongued Frog)**. BANGLADESH: SYLHET DIVISION: Golapganj (24.8583°N, 90.0208°E, WGS 84; > 200 m elev.). 1 June 2009. Md. Mukhlesur Rahman Khan. Department of Fisheries Biology and Genetics, Bangladesh Agricultural University, Mymensingh, Bangladesh. Specimen deposited at Institute for Amphibian Biology, Hiroshima University, Japan (IABHU 3784). Verified by Mitsuru Kuramoto. First locality record for Sylhet Division and only northeastern record for Bangladesh. Other records from Madhupur National Park, Mymensingh Division (ca. 210 km to W) (Mahony and Reza 2007. Herpetol. Rev. 38:350) and Chittagong Division (ca. 285 km to N), with no locality details, photograph, or voucher (Asmat et al. 2003. Univ. J. Zool., Univ. Rajshahi 22:141–143). Supported by Grant-in-Aids for Scientific Research (C) (17570082 and 20510216) to M. Sumida from the Ministry of Education, Culture, Sports, Science and Technology, Japan.

PSEUDACRIS CRUCIFER **(Spring Peeper)**. USA: GEORGIA: Lumpkin Co.: Chattahoochee National Forest near Dick's Creek Falls (34.67222°N, 83.90388°W; WGS 84; elev. 479 m). 08 May 2011. Leslie Phillips. Verified by John Jensen. UTADC 6940 photo voucher. New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. Univ. of Georgia Press, Athens. 575 pp.); previously documented in all adjacent counties with the exception of Fannin. Specimen was heard calling from the opposite side of the road from Dick's Creek at ~0130 h near the bridge at Corbin Crossing and found calling from a holly leaf.

LESLIE PHILLIPS, 57 Forsyth Street, 11H, Atlanta, Georgia 30303, USA (e-mail: lnphil08@gmail.com); **ROBERT L. HILL**, Department of Research and Conservation, Atlanta Botanical Garden, Atlanta, Georgia 30309, USA (e-mail: rhill@atlantabotanicalgarden.org).

TLALCOHYLA LOQUAX **(Rana Trepadora Sonorense; Mahogany Treefrog)**. HONDURAS: SANTA BÁRBARA: SW corner of Lago de Yojoa (14.800004°N, 88.000015°W, WGS84; 650 m elev.). 1 October 2010. James R. McCranie and Leonardo Valdés Orellana. Verified by Steve W. Gotte. USNM 578910. First record for Santa Bárbara, with the closest known locality being ca. 5 km E at 1.6 km N of Pito Solo, Comayagua (McCranie 2006. Smithson. Herpetol. Inform. Serv. 137:1–38). The frog was calling at night from low secondary vegetation surrounding a rain-filled swampy area.

JAMES R. McCRANIE, 10770 SW 164th Street, Miami, Florida 33157–2933, USA (e-mail: jmccrani@bellsouth.net); **LEONARDO VALDÉS ORELLANA**, Gerente General de "Hondufauna," Investigador Privado, Colonia América, Bloque 9, Casa 1806, Comayagüela, MDC, Honduras (e-mail: leovalor@hotmail.com).

CROCODYLIA — CROCODILIANS

ALLIGATOR MISSISSIPIENSIS **(American Alligator)**. USA: GEORGIA: Miller Co.: Mayhaw Wildlife Management Area (31.198069°N, 84.792064°W, WGS 84; elev. 48 m). 6 August 2011. Robert L. Hill. Verified by John Jensen. UTADC 6941. New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.); has been documented in adjacent Baker, Early, and Seminole counties. Has been previously observed in Miller Co., though this represents the first vouchered record. Two specimens observed from 0955–1035 h in water-filled borrow pit at entrance to Mayhaw Wildlife Management Area on Griggs-Lucille Rd ~2.23 km W of junction with Hwy 27.

ROBERT L. HILL, Department of Research and Conservation, Atlanta Botanical Garden, Atlanta, Georgia 30309, USA; e-mail: rhill@atlantabotanicalgarden.org.

TESTUDINES — TURTLES

APALONE FEROX **(Florida Softshell)**. USA: SOUTH CAROLINA: Allendale Co.: County road SSR-292 (33.02096°N, 81.27335°W;

WGS 84) adjacent to Stony Lake, 2.5 km NE Allendale. 5 May 2010. J. D. Camper. Verified by S. Miller. Clemson University Vertebrate Collections (CUSC 2820). Dead adult male on road next to a Carolina Bay. New county record (Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Institution Press, Washington D.C. 578 pp.).

JEFFREY D. CAMPER, Department of Biology, Francis Marion University, Florence, South Carolina, 29506, USA; e-mail: jcamper@fmarion.edu.

***APALONE SPINIFERA* (Spiny Softshell)**. USA: LOUISIANA: Vernon Parish: Kisatchie National Forest, Mill Creek Rd and Whiskey Chitto Creek crossing (31.0822°N, 93.14789°W; WGS 84). 11 July 2007. Stephen M. Ecrement. Florida Museum of Natural History, University of Florida (UF165499). Verified by Kenneth L. Krysko. First parish record; extends distribution N from Beauregard Parish, W from Rapides Parish, and S from Sabine and Natchitoches parishes as mapped by Dundee and Rossman (1989. The Amphibians and Reptiles of Louisiana. Louisiana State University Press, Baton Rouge. 300 pp.).

STEPHEN M. ECREMENT, Environmental and Natural Resources Management Division, Directorate of Public Works, Fort Polk, Louisiana 71459, USA; e-mail: Stephen.Ecrement@colostate.edu

***CHELYDRA SERPENTINA SERPENTINA* (Eastern Snapping Turtle)**. CANADA: ONTARIO: Kenora District: Woodland Caribou Provincial Park: S of Talon Lake (50.6550°N, 94.7795°W). 10 August 2009. Jeff King and Matt Butts. This specimen and all others listed below are photographic vouchers verified by Ross D. MacCulloch. Royal Ontario Museum. The GPS datum for all records is WGS 84. One adult (ROMdm 00255) was filmed basking on rocky shoreline. Nearest record is 38 km N from a small unnamed lake near Hammerhead Lake (Ontario Herpetofaunal Summary database [OHS] entry number 212801). Aubrey Township: near Aubrey Lake ca. 10 km E of City of Dryden (49.7667°N, 92.9833°W). June/July 2007. Ray Schott. One adult (ROMdm 00256) found in grassy area. First township record. Nearest record is 24 km SE from Godson Lake on Highway 502 (NMC 24616, OHS 101519). MacNicol Township: Dixie Lake Rest Area, ca. 30 km E of City of Kenora on Highway 17 (49.8337°N, 93.9467°W). 13 July 2008. Graham Suffield. One adult (ROM dm 00264) swimming along rocky lakeshore. First township record. Nearest record 51 km E near Trial Lake in Buller Township (OHS 258765). Stokes Township: Gullwing Creek, ca. 12 km N of City of Dryden (49.8500°N, 92.9500°W). June/July 2007. Ray Schott. One adult (ROMdm 00257) found on cobbled bank. First township record. Nearest record 30 km SE from Godson Lake on Highway 502 (NMC 24616, OHS 101519). Unorganized township: Trap Lake, ca. 10 km S of City of Dryden (49.6500°N, 92.7833°W). June/July 2007. Ray Schott. One adult (33 cm CL, ROMdm 00258) caught in a trap net during fisheries work. New locality record. Nearest record 5 km S from Godson Lake on Highway 502 (NMC 24616, OHS 101519).

Rainy River District: Lake of the Woods Municipality (former Morson Township): Village of Morson, S end of Lake of the Woods (49.095056°N, 94.320681°W). 16 May 2008. Cheryl Gauthier. One adult (ROMdm 00262) on beach in small bay. First township record. Nearest record 13 km NE at Walden Island (OHS 59429). Quetico Provincial Park: Pickerel River between Pickerel and French Lakes (48.654°N, 91.177°W; WGS 84). 09 August 2008. Graham McGuire. One adult (ROMdm 00263) swimming in river. New locality record. Nearest record is ca. 5 km N from Eva Lake (OHS 111040). Unorganized township: Niobe Lake, near Village of Sapawe (48.732094°N, 91.319192°W). August 2004. Jeffrey N. Robinson. One adult (ROMdm 00266) caught in net during fisheries study. New locality record. Nearest record is 12 km E from Eva Lake (OHS 111040).

Thunder Bay District: Devon Township: Highway 593 N of Highway 61 and S of Highway 588 (48.083983°N, 89.802704°W). June 2004. Jeffrey N. Robinson. One juvenile (ROMdm 00267) captured in center of the highway. First township record. Nearest record 82 km E from Sibley Provincial Park (OHS 111265). Lybster Township: Village of Nolalu, near bridge on Old Mill Road (48.291972°N, 89.808882°W). July 2008. Robert Kamstra and Stephen J. Hecnar. One adult (18.7 cm CL, 1478 g; ROMdm 00265) found dead on roadside. Specimen photographed and placed in Lakehead University Biology collection (LUB 00227). First township record. Nearest record 74 km E from Sibley Provincial Park (OHS 111265). Inwood Township: Highway 17 ca. 4.8 km E of Town of Upsala (49.021372°N, 90.442424°W). 31 May 2008. Brent Gibbons. One adult female (29 cm CL) (ROMdm 00260) attempting to cross highway between lakes was captured and moved to other side. Specimen subsequently oviposited on sandy beach of Inwood Park Lake. First township record. Nearest record 64 km SW from Eva Lake (48.69539°N, 91.16547°W; OHS 111040). Laurie Township: near Matawin River ca. 3.8 km SW of Shabaqua railway crossing (48.545059°N, 89.928092°W). 13 June 2007. Herbert Bax. One adult (ROMdm 00261) found on log haul road near coniferous forest cutover. First township record. Nearest record 27 km E from Gravel Lake in Hardwick Township (OHS 266100).

Algoma District: Dahl Township. Highway 17 ca. 30 m from Normandy Lodge Road. (48.2987°N, 84.9659°W). 02 September 2005. F. Neil Dawson. One adult on shoulder of highway (ROMdm 00259). First township record. Record lies in a large gap between northwestern and northcentral Ontario records and may extend range to NE. Nearest records are 98 km W in Pukaskwa National Park (Ontario Herpetofaunal Summary, entry number 20279) and 37 km S in Wawa, Ontario (COSEWIC 2008. COSEWIC Assessment and Status Report on the Snapping Turtle *Chelydra serpentina* in Canada. Committee on the Status of Endangered Wildlife in Canada, Ottawa. vii + 47 pp.). These two records were suspected introductions but the new record suggests that the gap may be an artifact of insufficient sampling in the region. The specimens we report are significant because they represent new localities from areas of limited sampling near the presumed northern range limit for the species in the boreal region of Ontario (Schueler 1976. Blue Jay 34[1]:18–25).

***CHELYDRA SERPENTINA SERPENTINA* (Eastern Snapping Turtle)**. USA: HAWAII: OAHU: Honolulu Co.: Kaneohe: Kamooalii Stream, within the Ho'omaluhia Botanical Garden (21.3840°N, 157.8025°W; WGS 84). 25 May 2011: Bishop Museum (BPBM 37715). Collected by Tag N. Engstrom. Verified by Allen Allison (BPBM). First vouchered record of a wild-caught

Chelydra serpentina from the state of Hawaii (Yamamoto and Tagawa 2000. Hawai'i's Native and Exotic Freshwater Animals. Mutual Publishing, Honolulu, Hawaii. 200 pp.). A mature male was captured in a funnel trap in the small reservoir above Lehua Dam in Kamooalii stream, in the Ho'omaluhia Botanical Garden. A previous, unconfirmed report of a snapping turtle in a different body of water in the botanical garden suggests that there may be an established population at this location. Introduction of another large non-native predator to the aquatic ecosystem of Hawaii could have major negative effects.

TAG N. ENGSTROM, Department of Biological Sciences, California State University Chico, Chico, California 95929-0515, USA; e-mail: tengstrom@csuchico.edu.

***GRAPTEMYS BARBOURI* (Barbour's Map Turtle)**. USA: Georgia: Coweta and Spalding Cos.: Two adult females observed and photographed basking on a log in Line Creek (which forms the boundary between the two counties) at the Georgia Highway 16 bridge (33.256694°N, 84.497399°W; NAD 83). 7 July 2011. John B. Jensen. Verified by Sean Graham. AUM AHAP-D 317, photographic voucher. First county and creek records, as well as an upstream (Flint River drainage) and northerly range extension of approximately 15 river-km from a Flint River record in Meriwether Co. (Jensen et al. [eds.] 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.).

JOHN B. JENSEN, Georgia Department of Natural Resources, Nongame Conservation Section, 116 Rum Creek Drive, Forsyth, Georgia 31029, USA; e-mail: john.jensen@gadnr.org.

***GRAPTEMYS GEOGRAPHICA* (Northern Map Turtle)**. USA: GEORGIA: Floyd Co.: 1.15 km W Black Buff Road. Multiple individuals were observed and photographed in the Coosa River near Rome (34.20591°N, 85.29058°W; NAD 83). 5 August 2011. Grover Brown and Owen Kinney. Verified by Kenneth L. Krysko. UF 165620. New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.). This record conservatively fills a 475 km distribution gap between previous Coosa River drainage records upstream in the Conasauga River in Whitfield Co., Georgia (GMNH 19514) and the only other Coosa River record, a vague record downstream in Coosa Co., Alabama (Mount 1975. The Reptiles and Amphibians of Alabama. Auburn Univ. Agric. Exp. Stat. 347 pp.).

McCRANIE, 10770 SW 164th Street, Miami, Florida 33157–2933, USA (e-mail: jmccrani@bellsouth.net); **LEONARDO VALDÉS ORELLANA**, Gerente General de "Hondufauna," Investigador Privado, Colonia América, Bloque 9, Casa 1806, Comayagüela, MDC, Honduras (e-mail: leovalor@hotmail.com); **ALEXANDER GUTSCHE**, Museum für Naturkunde, Herpetologie, Invalidenstr. 43, D-10115 Berlin, Germany (e-mail: alexander-gutsche@web.de).

***MACROCHELYS TEMMINCKII* (Alligator Snapping Turtle)**. USA: GEORGIA: Clayton Co.: Flint River, 0.35 km S of McDonough Road (33.45604°N, 84.38425°W; NAD 83). 21 July 2011. John B. Jensen and Sean P. Graham. UF 165542. Coweta Co.: Hutchins Lake, 0.24 km NW Rockaway Road (33.31982°N, 84.54592°W; WGS 84). August 2010. Clint Freeman. UF 165217. Fayette Co.: Flint River 0.29 km N of McDonough Road (33.46100°N, 84.38306°W; NAD 83). 21 July 2011. John B. Jensen and Sean P. Graham. UF 165541. Spalding Co.: Flint River, 0.76 km SW of Georgia Highway 16 (33.23941°N, 84.43340°W; NAD 83). 15 July 2011. John B. Jensen and Kristina Sorensen. UF 165533. Each record reported herein is a first record for their respective county (Jensen et al. [eds.] 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp). All specimens were verified by Kenneth Krysko.

During summer 2010, one of us (JBJ) was sent a photograph of a large, adult male alligator snapper from an impounded tributary (Keg Creek; Hutchins Lake) of the Flint River, which represented a significant upstream and northerly range extension well into the Piedmont physiographic province. This discovery led us to trap two other Piedmont stretches of the Flint River drainage to determine how widespread *M. temminckii* might be in what has largely been dismissed by biologists and former commercial trappers as habitat too far upstream and away from the Coastal Plain to harbor the species. In fact, Al Redmond, perhaps the most well-known commercial trapper of this species in Georgia, considered the Flint River near Reynolds, approximately 100 air-km S of our northernmost record and within the Coastal Plain physiographic region, to be the northern limit of the species' Georgia range (pers. comm. to P. Pritchard *in* Pritchard 2006. The Alligator Snapping Turtle: Biology and Conservation. Krieger Publishing Co., Malabar, Florida. 140 pp.). Our trapping effort yielded 13 alligator snappers in 19 trap-nights (TN), for a catch per unit effort (CPUE) of 0.68 turtles/TN. Of the 13 alligator snappers captured, eleven were juveniles. In a statewide status survey of this species from 1997–2001, Jensen and Birkhead

(2003. Southeast. Nat. 2:25–34) had a total CPUE of 0.20 turtles/TN in 281 TN, with the best stream producing a CPUE of 0.45 turtles/TN. Additionally, captures as part of the previous study resulted in a 4:1 adult:juvenile ratio. Clearly, the recently trapped Piedmont portion of the Flint River drainage appears to have a relatively dense and successfully recruiting population of this state "Threatened" species, perhaps because commercial trappers did not think they occurred there.

and Reptiles of Nebraska. Rusty Lizard Press, Oro Valley, Arizona. 400 pp.; Fogell 2010. A Field Guide to the Amphibians and Reptiles of Nebraska. University of Nebraska, Lincoln. vi + 158 pp.). Fills distributional gap in northwestern Nebraska among Sheridan, Sioux, Scottsbluff, and Morrill counties. Female photographed on shoulder of highway near the western edge of the Sandhill Region of Nebraska.

ANTHONY E. BRIDGER, Department of Biology, University of Nebraska at Kearney, Kearney, Nebraska 68849, USA; e-mail: tony.bridger@hotmail.com.

***TRACHEMYS STEJNEGERI* (Central Antillean Slider)**. USA: PUERTO RICO: Isla de Culebra (18.31°N, 65.28°W; WGS 84), 3–26 m elev. Twenty-six live *Trachemys stejnegeri* (10 males, 13 females, 2 juveniles, 1 unknown) were observed along a small, forested stream on the south side of Culebra Island by M. T. Jones and L. L. Willey. 1–2 January 2011. Verified by M. E. Seidel. Museum of Comparative Zoology (digital image MCZ R-188664).

Trachemys stejnegeri utilizes a variety of wetlands on Great Inagua (Bahamas), Hispaniola, and Puerto Rico. Of three subspecies, the nominate race *T. s. stejnegeri* occurs throughout the island of Puerto Rico. Seidel (1988. Am. Mus. Novit. 2918:1–41) cited anecdotal reports of *T. stejnegeri* from both Isla de Culebra and neighboring Isla de Vieques, located 30 and 10 km from the eastern shore of Puerto Rico, respectively. Subsequent authors (e.g., Ernst et al. 2010. Turtles of the World online database: *Trachemys stejnegeri* [http://nlbif.eti.uva.nl/bis/turtles.php?menuentry=soorten&id=327]; Iverson et al. 2010. EMYSystem: *Trachemys stejnegeri* (http://emys.geo.orst.edu/collection/species/Trachemysstejnegeri/Trachemysstejnegeri.htm) have indicated that the species is present on Culebra and Vieques, citing Siedel's (1988, *op. cit.)* unverified report.

Our findings confirm the presence of an established population of *T. stejnegeri* on Culebra. We observed *T. stejnegeri* in a variety of habitats: basking on rocks, submerged in shallow pools along the stream and one turtle in a stone cistern about 15 m from the stream channel. All sliders observed were consistent with the nominate subspecies *T. s. stejnegeri*, native to Puerto Rico.

Female SCL_{min} averaged 194 mm (N =12; range = 162–267 mm). Male SCL_{min} averaged 156 mm (N = 9; range = 124–184 mm). Five of nine males were melanistic, which is typical for the species (Seidel 1988, *op. cit.).*

We observed courtship in a shallow (20 cm) pool on 2 January 2011. Combined with the presence of juveniles, this suggests that the population is reproducing. Channel slope (= stream gradient) averaged 3.1%. Streamflow averaged 0.0112 m^3/sec. The stream may now be augmented by discharge from a municipal water facility located in its headwaters, but the channel is clearly visible in aerial images (U.S. Geological Survey) taken in 1994, before the facility existed. Total dissolved solids in the stream at 20 m elev. (4.6 ppt) indicate brackish origin, but within the range tolerated by *Trachemys* and *Pseudemys* in the Cayman Islands and Florida (Dunson and Seidel 1986. J. Herpetol. 20[2]:237–245).

We thank J. Rosado and J. Martinez of the MCZ for help accessioning digital photographs, and M. Seidel for valuable feedback on earlier versions of this note. B. Mobbs and T. Jones provided excellent field support.

MICHAEL T. JONES (e-mail: mtjones@bio.umass.edu) and **LISABETH L. WILLEY**, Department of Environmental Conservation, University of Massachusetts, Amherst, Massachusetts 01003, USA (e-mail: lwilley@cns.umass.edu)

SQUAMATA — LIZARDS

***ACANTHODACTYLUS BOSKIANUS* (Bosc's Fringe-toed Lizard)**. IRAN: KHUZISTAN PROVINCE: ca. 30 km N of Dezful, around Vahdati village (32.6333°N, 48.5833°E; 220 m elev.; datum WGS 84). Collected by Roman Nazarov and Mehdi Rajabizadeh. International Center for Science, High Technology and Environmental Sciences Zoological Museum, Kerman (ICSTZM 6H1285). Verified by Nasrullah Rastegar-Pouyani. Associated with annual grasses, *Amygdalus* and Graminaceae as dominant vegetation in lowland sandy hills. First confirmed record for Khuzistan Province, and 500 km S of only record (Rastegar-Pouyani 1999. Asiatic Herpetol. Res. 8:85–89). Our specimens fit diagnosis and color pattern given in Anderson (1999. The Lizards of Iran. Society for the Study of Amphibians and Reptiles, Ithaca, New York. 415 pp.).

ROMAN NAZAROV, Zoological Museum of Moscow State University Herpetology Department, 125009 Moscow, B. Nikitskaya 6, Russia (e-mail: r_nazarov@mail.ru); **MAHDI RAJABIZADEH**, Department of Biodiversity, Institute of Environmental Sciences, International Center for Science, High Technology and Environmental Sciences, Kerman, Iran (e-mail: khosro.rajabizadeh@gmail.com; **NASTARAN HEIDARI**, Department of Biology, Faculty of Science, Razi University, Kermanshah, Iran (e-mail: heydari.ns@gmail.com); **HIVA FAIZI**, Department of Biology, Faculty of Science, Razi University, Kermanshah, Iran (e-mail: hiwa.faizi@gmail.com).

***ASPIDOSCELIS LAREDOENSIS* (Laredo Striped Whiptail)**. USA: TEXAS: Kinney Co.: Rancho Rio Grande, 10–110 m from the Rio Grande (29.159721°N, 100.757492°W; datum WGS84, elev. 250 m), 6.08 km SW (all distances in straight lines) from the nearest point on US Hwy 277 (29.191475°N, 100.706570°W; WGS 84; elev. 268 m). 14 June 2000. James E. Cordes. University of Arkansas "Department of Zoology" (UADZ) 6731 (65 mm SVL), 6734 (78 mm SVL), 6738 (79 mm SVL). Verified by Mark A. Paulissen. First county record (Dixon 2000. Amphibians and Reptiles of Texas. Texas A & M Univ. Press, College Station. 421 pp.).

With reference to previous sites reported for *A. laredoensis* in the northern part of its range (Walker 1987. Texas J. Sci. 39:313–334), the new site is ca. 25 km SE of Del Rio, Val Verde Co., and ca. 56 km NW of Eagle Pass, Maverick Co., and fills in an apparent disjunction in the range (Walker 1987, *op. cit.*) . Based on collection data obtained on Rancho Rio Grande by JEC in May and June 2000, gonochoristic *A. gularis* was euryecious (present throughout the ranch), ubiquitous (regularly observed), and readily collectible (N = 118), whereas diploid parthenogenetic *A. laredoensis* B was stenoecious (restricted to a few areas influenced by the river) and rarely encountered or collected (N = 7).

Specimens were collected under authority of Texas Parks and Wildlife Department (TPWD) permit SPR-1090-298 to James E. Cordes. David H. Riskind and Mark Lockwood of TPWD made it possible for us to conduct herpetological studies in Texas. Research on the private ranch was enabled by consent, advice, and/or guidance provided by Bill Moody (owner), John and Elizabeth Kincaid (ranch foreman and spouse), Aurelio Castillo (ranch hand), and Bubba and the other federal Tick Riders (livestock disease abatement) who ply the border on horseback.

JAMES E. CORDES, Division of Sciences and Mathematics, Louisiana State University Eunice, Eunice, Louisiana 70535, USA (e-mail: jcordes@lsue.edu); **JAMES M. WALKER**, Department of Biological Sciences, University of Arkansas, Fayetteville, Arkansas 72701, USA (e-mail: jmwalker@uark.edu).

***ASPIDOSCELIS NEOMEXICANA* (New Mexico Whiptail)**. USA: NEW MEXICO: Roosevelt Co.: 0.48 km E of De Baca-Roosevelt counties boundary in highly disturbed habitat near US Hwy 84/60 and BNSF railroad grade (34.450833°N, 103.942500°W; WGS 84; elev. 1288 ± 2 m WAAS). 10 July 2011. James E. Cordes. University of Arkansas "Department of Zoology" (UADZ 8898). SVL 71 mm. Verified by Harry L. Taylor. New county record. (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque, 431 pp.). This location for this allodiploid parthenogen is ~27.8 km straight-line east of the nearest locality in Fort Sumner (34.479722°N, 104.228889°W; WGS84; elev. 1260 m), De Baca Co. (Taylor 2002. Herpetol. Rev. 33:223–224; Manning et al. 2005. Am. Mus. Novitat. 3492:1–56; Manning and Walker 2006. Am. Midl. Nat. 155:411–416), situated farther east in New Mexico than the records for the species at Conchas Lake (35.377222°N, 104.184444°W; WGS84; elev. 1271 m), San Miguel Co. (Leuck et al. 1981. Southwest. Nat. 26:72–74; Manning et al., *op. cit.*), and also inhabited by gonochoristic *A. sexlineata* with which it hybridizes (Cordes, unpubl.). Discovery of *A. neomexicana* in Roosevelt Co. also provides another detail of distribution for consideration in the controversy on whether the species is naturally occurring in De Baca, San Miguel, and Roosevelt counties (Walker et al. 1992. Southwest Nat. 37:82–86; Taylor, *op. cit.*; Manning et al., *op. cit.*) or the result of introductions of individuals (Leuck et al., *op. cit.*; Persons and Wright 1999. Herpetol. Rev. 30:207–209) well east of the main distribution area in the Rio Grande Valley in New Mexico.

Collections were made under authority of New Mexico Game and Fish permit number 1850 to James E. Cordes.

***CTENOSAURA HEMILOPHA* (San Esteban Island Iguana)**. MÉXICO: SONORA: Municipality of Hermosillo: Isla Alcatráz (28.813289°N, 111.96685°W; WGS84). 24 July 2005. Víctor Hugo Reynoso and Georgina González Monfil. Verified by Eugenia Zarza Franco. CNAR-IBH-RF 34-35. First record from Isla Alcatráz, extending its known range 35 km NE of Isla Cholludo (Grismer 2002. Amphibians and Reptiles of Baja California: Including its Pacific Islands and the Islands in the Sea of Cortez. Univ. of California Press, Berkeley. xiii + 399 pp.). This species is probably of recent introduction. One lizard was found in a hole on a cliff and the other on the ground below large rocks; both were in an arid environment.

GONZÁLEZ HERNÁNDEZ,** Colección Nacional de Anfibios y Reptiles, Instituto de Biología, Departamento de Zoología, Universidad Nacional Autónoma de México, circuito Exterior s/n, Ciudad Universitaria, México D.F., C.P. 04510.

***CTENOSAURA SIMILIS* (Gray's Spiny-tailed Iguana)**. USA: FLORIDA: Monroe Co.: Big Pine Key 1.08 km SE of jct. Gulf Boulevard and Key Deer Boulevard (24.71265°N, 81.38109°W; WGS 84; elev. <3 m). 19 May 2011. Chad Anderson. Verified by Kenneth L. Krysko. Florida Museum of Natural History photo voucher (UF 165529). New island record and second island record from the Florida Keys (Enge et al. 2006. Herpetol. Rev. 37:494). Adult photographed at 1144 h by a Wildgame™ passive infared camera positioned near the carcass of a Key Deer (*Odocoileus virginianus clavium*) in pine rockland habitat. The sighting was 5.2 km W of a *C. similis* sighting on adjacent No Name Key, where a reproducing population apparently exists (Enge et al., *op. cit.*).

CHAD ANDERSON, National Key Deer Refuge, 28950 Watson Boulevard, Big Pine Key, Florida 33043, USA (e-mail: Chad_Anderson@fws.gov); **KEVIN M. ENGE**, Florida Fish and Wildlife Conservation Commission, 1105 SW Williston Road, Gainesville, Florida 32641, USA (e-mail: kevin.enge@myfwc.com).

***GONATODES ALBOGULARIS* (Yellow-headed Cecko; Geco Cabeza Amarilla)**. HONDURAS: EL PARAÍSO: Mapachín (13.9830°N, 86.4910°W, WGS84; 800 m elev.). 8 July 2010. James R. McCranie and Leonardo Valdés Orellana. Verified by Steve W. Gotte. USNM 578912–14. First records for El Paraíso, with the closest known locality being ca. 45 km NNW at Villa San Francisco, Francisco Morazán (USNM 578915–16). The lizards was found during the day in stacked roofing tiles in the yard of a resident.

LEONARDO VALDÉS ORELLANA, Gerente General de "Hondufauna," Investigador Privado, Colonia América, Bloque 9, Casa 1806, Comayagüela, MDC, Honduras (e-mail: leovalor@hotmail.com); **JAMES R. McCRANIE**, 10770 SW 164th Street, Miami, Florida 33157–2933, USA (e-mail: jmccranie@bellsouth.net).

***HEMIDACTYLUS TURCICUS* (Mediterranean House Gecko)**. PORTUGAL: SETÚBAL: ca. 38.5167°N, 08.9047°W (WGS84). 24 July 2011. Luis Ceríaco. Photographic vouchers deposited at Colecção Fotográfica of the Museu de Ciências Naturais da Escola Secundária André de Gouveia (MCN/MB/F/R/16). Verified by Ana Pires. Species previously unrecorded from region, nearest population being at least 90 km E, in Évora region (Mateus and

Jacinto 2010. *In* Loureiro et al. [eds.], Atlas dos Anfíbios e Répteis de Portugal, pp. 130–131. Esfera do Caos Editores, Lisboa). Specimen observed on wall near dock, at ca. 2130 h. Presence of species in Setubal may be due to human-mediated dispersal, a common dispersal mode for species (Locey and Stone 2006. J. Herpetol. 40:526–530).

LUIS MIGUEL PIRES CERÍACO, Projecto "Salvem as Osgas!" and Centro de Estudos de História e Filosofia da Ciência, Universidade de Évora, Bairro do Bacelo, Rua do Viveiro nº 5D, 7005–638 Évora, Portugal; e-mail: luisceriaco@netcabo.pt.

***HEMIDACTYLUS TURCICUS* (Mediterranean Gecko)**. USA: ALABAMA: Shelby Co.: University of Montevallo's Regional In-Service Education Center, 2790 Pelham Parkway, Pelham (33.30904°N, 86.80465°W; WGS84/NAD83). 1 April 2011. R. Birkhead. Verified by Craig Guyer (digital image vouchers AUM AHAP-D 312–313). Two desiccated specimens removed from glue traps set for pest control. New county record.

Hemidactylus turcicus has been documented in many of the larger cities in Alabama (Mount 1996. The Reptiles and Amphibians of Alabama. University of Alabama Press. xi+347 pp.). The geckos were captured in a warehouse where packaging and refurbishing kits for the Alabama Math Science and Technology Initiative (AMSTI) occurs. A total of four traps were examined and all contained at least one *H. turcicus*. It is reasonable to assume that the warehouse harbors a breeding population and geckos are quite likely making into the crates of material being packaged and delivered to all the K-8 schools in the area.

Thanks go to Sean Graham for reviewing this note.

ROGER D. BIRKHEAD, Alabama Science In Motion, Auburn University, Alabama 36849-5414, USA; e-mail: birkhrd@auburn.edu

***HEMIDACTYLUS TURCICUS* (Mediterranean Gecko)**. USA: OKLAHOMA: Comanche Co.: Lawton: exterior wall at 1709 NW Cache Rd, the Deluxe Inn Motel (34.623889°N, 098.416111°W; WGS 84). 04 July 2011. Cameron University Museum of Zoology (CUMZ 215). Collected by Jared W. White. Verified by Stanley F. Fox. New county record (Sievert and Sievert 2011. A Field Guide to Oklahoma's Amphibians and Reptiles, 3rd ed. Oklahoma Department of Wildlife Conservation. Oklahoma City, Oklahoma. 211pp.). Numerous adults and juveniles were found within a five-block radius of the specimen collection site. The nearest documented population is 82.3 km S in Wichita Co., Texas (Dixon 2000. Amphibians and Reptiles of Texas. Texas A&M University Press, College Station. 419 pp.). Several counties in eastern and central Oklahoma have documented populations, but all are greater than 100 km distant (Sievert and Sievert 2011, *op. cit.)*

JARED W. WHITE (e-mail: Jared.White@cameron.edu), **ERIC J. BECK**, and **MICHAEL S. HUSAK** (e-mail: michaelh@cameron.edu), Department of Biological Sciences, Cameron University, Lawton, Oklahoma 73505, USA.

***LEIOCEPHALUS CARINATUS* (Northern Curly-tailed Lizard)**. USA: FLORIDA: Pinellas Co.: Indian Rocks Beach, 9th Ave. N, 0.03 km W of Gulf Blvd. (27.8914°N, 82.8498°W; WGS 84). 29 July 2011. J. Steve Godley. Verified by Kenneth L. Krysko. (UF 165670 and 165671, and USNM 562740 and 562741). New county record. On the west coast of Florida this species has been reported from Collier Co. (McCoid 2002. Herpetol. Rev. 33:322) and Lee Co. 166.7 km to S (Campbell and Klowden 2003. Herpetol. Rev. 34:384;), an unpublished UF record (UF 159751, K. L. Krysko, pers. comm.) from Pasco Co., 36.5 km to N (review of Pasco Co. locality suggests the specimen was a waif with no established population). The Indian Rocks Beach population (ca. 10 adults of multiple size classes) seemed restricted to a two-block area. An expanded search of 2.2 km of Gulf Blvd. yielded no additional animals. Residents first noticed the species in ca. 2006 after city workers mulched beach access flower beds.

***PLESTIODON LATICEPS* (Broad-headed Skink)**. USA: TENNESSEE Madison Co.: Lowell Thomas Drive behind TWRA Region 1 office (35.3744°N, 88.4330°W, NAD 83). 10 May 2011. Robert Colvin. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 19129). First county record (Scott and Redmond 2008. Atlas of Reptiles in Tennessee. Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. http://www.apsu.edu/reptatlas [updated 26 July 2011; accessed 12 September 2011].

Voucher specimen collected under the authority of the Tennessee Wildlife Resources Agency; field work supported by State Wildlife Grant (SWG) funding under the authority of the U.S. Fish and Wildlife Service.

ROBERT COLVIN, Tennessee Wildlife Resources Agency, Region I, 200 Lowell Thomas Drive, Jackson, Tennessee 38301, USA; e-mail: Rob.Colvin@tn.gov.

***SCINCELLA LATERALIS* (Little Brown Skink)**. USA.: INDIANA: Jackson Co.: Knobstone Glade Nature Preserve (38.82692°N, 86.06776°W; NAD 83). 1 June 2011. Sarabeth Klueh and Jason Mirtl. Verified by Chris Phillips. Illinois Natural History Survey (INHS 2011k). New county record (Minton 2001. Amphibians and Reptiles of Indiana, 2nd ed., revised. Indiana Academy of Science. vii–404 pp.) One adult out in the open in leaf litter.

SARABETH KLUEH (e-mail: sklueh@dnr.in.gov) and **JASON MIRTL**, Wildlife Diversity Section, Indiana Department of Natural Resources Division of Fish and Wildlife, 553 E. Miller Drive, Bloomington, Indiana 47401, USA.

STROBILURUS TORQUATUS. BRAZIL: MINAS GERAIS: UHE Barra do Braúna (ca. 21.4451°S, 42.4288°W, datum SAD69). J. P. Barbosa. 11 May 2009. Museu de Zoologia João Moojen, Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil (MZUFV 860, SVL = 74 mm; MZUFV 861, SVL = 79 mm). Verified by D. Loebmann. This apparently rare lizard is known to occur in the Atlantic Forest of the Brazilian states of Ceará, Pernambuco, Alagoas, Bahia, and Espírito Santo, inhabiting both undisturbed and secondary forests (Borges-Nojosa and Caramaschi 2003 *In* L. R. Leal et al. [eds.], Ecologia e Conservação da Caatinga, pp. 463–512. Universidade Federal de Pernambuco, Recife, Brazil; Jackson 1978. Arq. Zool. 30[1]:1–79; Rodrigues et al. 1989. Rev. Brasil. Genet. 12[4]:747–759). The present note establishes the westernmost record of *S. torquatus*, and the first report of this species for the state of Minas Gerais, about 270 km straightline southwest from Aracruz, state of Espírito Santo, the closest known locality (Jackson 1978, *op. cit.*).

HENRIQUE CALDEIRA COSTA, Museu de Zoologia João Moojen, Vila Gianetti 32, Universidade Federal de Viçosa, CEP 36570-000, Viçosa, Minas Gerais, Brazil; e-mail: ccostah@yahoo.com.br.

***TARENTOLA MAURITANICA* (Moorish Gecko)**. PORTUGAL: TORRES VEDRAS: ca. 39.0197°N, 0.25779°W (WGS84). 24 July 2011. Collected by Mariana Marques. Colecção de Animais em formol of Museu de Ciências Naturais da Escola Secundária André de Gouveia (MCN/MB/AC/V/46). Species previously unreported from region, nearest population being at least 10 km S, in Mafra region (Perera et al. 2010. *In* Loureiro et al. [eds.], Atlas dos Anfíbios e Répteis de Portugal, pp. 132–133. Esfera do Caos Editores, Lisboa). Specimen collected from wall in urban environment, at ca. 2200 h. Many other individuals sighted in urban areas of Torres Vedras, where it is abundant. ÉVORA: ca. 38.5708°N, 07.9083°W. 27 May 2011. Luis Ceríaco. Photographic vouchers (MCN/MB/F/R/11). Species previously unreported from region, nearest population being at least 15 km SW (Perera et al. 2010, *op. cit.*). Specimen photographed on wall in urban environment, at ca. 2230 h. Many individuals sighted in urban areas of Évora, where it is abundant and occurs sympatrically with *Hemidactylus turcicus*. All specimens were verified by Ana Pires.

LUIS MIGUEL PIRES CERÍACO, Projecto "Salvem as Osgas!" and Centro de Estudos de História e Filosofia da Ciência, Universidade de Évora, Bairro do Bacelo, Rua do Viveiro nº 5D, 7005–638 Évora, Portugal (e-mail: luisceriaco@netcabo.pt); **MARIANA PIMENTEL MARQUES**, Projecto "Salvem as Osgas!" and Escola de Ciências e Tecnologias, Universidade de Évora.

***TRETIOSCINCUS ORIXIMINENSIS* (Oriximina Lizard)**. COLOMBIA: VAUPÉS: Serranía del Taraira (1.063875°S, 69.532764°W; datum Bogotá WGS 84). 01 August 1993. I. Stephen Ayala. Colección de Reptiles, Instituto de Ciencias Naturales, Universidad Nacional de Colombia, Colombia (ICN 7094). Mitú (1.1944167°S, 70.2399167°W). 14 July 2010. M. Calderón-Espinosa. ICN 12072. Verified by Juan E. Carvajal-Cogollo. This lizard was known from Venezuela in the Territorio Federal of the state of Amazonas at the confluence of Rio Mavaca and Rio Orinoco, upper Rio Mavaca and Rio Mawarinuma localities, and in Brazil in Amazonas state in Rio Negro, Tapurucuara locality and Oriximiná, Para state (in lower Rio Trombetas locality) (Ávila-Pires 1995. Lizards of Brazilian Amazonia [Reptilia: Squamata]. Zoologisches Verhandelingen, Leiden 299:1–706; Ávila-Pires 2005. *In* Hollowell and Reynolds [eds.], Checklist of the Terrestrial Vertebrates of the Guiana Shield. Bull. Biol. Soc. Washington 13:25–42). Avila-Pires (1995, 2005, *op. cit.*) suggested that this species might occur in Colombia and the present specimens confirm this prediction. These are the first records for Colombia, extending the known range to "Amazonía de Colombia," 450 km SW from nearest locality (Oriximiná, Pará, Brazil, the type locality; Avila-Pires 1995, *op. cit.*).

SQUAMATA — SNAKES

***BOTHROPS ASPER* (Terciopelo)**. MÉXICO: HIDALGO: Municipality of Huehuetla; Barrio Aztlán (98.0822°N, 20.4666°W; WSG84), 566 m elev. 21 August 2008. Froylán Ramírez and Nallely Morales. Verified by Jesús M. Castillo. Colección Herpetológica, Centro de Investigaciones Biológicas, Universidad Autónoma del Estado de Hidalgo (CH-CIB 1635). First municipality record, extending its range in the state ca. 91 km SE from its closest known locality at Molango, Acayuca (Ramírez-Bautista et al. 2010. Lista Anotada de los Anfibios y Reptiles del Estado de Hidalgo, México. Universidad Autónoma del Estado de Hidalgo, CONABIO. x + 104 pp.). The snake was found in tropical deciduous forest. Fieldwork was funded by CONACyT- 95828.

IRENE GOYENECHEA (e-mail: ireneg28@gmail.com), **NALLELY MORALES-CAPELLAN,** and **LEONARDO FERNÁNDEZ-BADILLO**, Centro de Investigaciones Biológicas (CIB), Universidad Autónoma del Estado de Hidalgo, A. P. 1-69 Plaza Juárez, Pachuca, Hidalgo, México.

***CHIRONIUS FLAVOLINEATUS* (Liana Snake)**. BRAZIL: RONDÔNIA: Pimenta Bueno (11.39°S, 61.11°W, SAD 69; 195 m elev). 26 May 2007. S. de Albuquerque. Coleção Herpetologica da Universidade Federal do Acre-Campus Floresta, Cruzeiro do Sul, Acre, Brazil (UFACF 1280). Verified by A. J. Suzart Argôlo. Specimen was found in patches of "cerrado" areas inside the Amazonian domain. This species is known in Brazil from west Pernambuco and Ceará states, Mato Grosso, Tocantins, Pará, Goiás, Minas Gerais; central and northeastern litoral of the Bahia state, and Central São Paulo state; also known from northeastern Paraguay; and central Bolivia (Borges-Nojosa and Lima 2009. Herpetol. Rev. 40:237; Cunha and Nascimento 1978. Publ. Avul. Mus. Paraense Emílio Goeldi 32:1–218; Dixon et al. 1993. Revision of the Neotropical Snakes Genus *Chironius* Fitzinger [Serpentes, Colubridae]. Museo Regionale di Scienze Naturali – Torino, 279 pp.; Freitas and Silva 2007. Herpetofauna das Caatingas e Áreas de Altitudes do Nordeste Brasileiro, USEB, Pelotas, 388 pp.). In Brazil, the western limit of the species range is central Mato Grosso state (Dixon et al., *op. cit.*). First state record, extends the species range 400 km N from Mato Grosso State (Dixon et al., *op. cit.*).

IRENE GOYENECHEA (e-mail: ireneg28@gmail.com), **NALLELY MORALES-CAPELLAN**, and **LEONARDO FERNÁNDEZ-BADILLO**, Centro de Investigaciones Biológicas (CIB), Universidad Autónoma del Estado de Hidalgo, A.P. 1-69 Plaza Juárez, Pachuca, Hidalgo, México.

CROTALUS HORRIDUS **(Timber Rattlesnake)**. USA: ARKANSAS: Lonoke Co.: vicinity of Austin, AR Hwy 319; 8 km W US167 (35.055503°N, 92.039536°W; WGS 84). 27 August 2011. V. Wilson. Verified by S. E. Trauth. Arkansas State University Museum of Zoology Herpetology Collection (photo voucher ASUMZ 31830). New county record partially filling a distributional hiatus in central Arkansas (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. University of Arkansas Press, Fayetteville. 421 pp.). This adult individual was discovered in a residential backyard and was subsequently released unharmed.

MATTHEW B. CONNIOR, Health and Natural Sciences, South Arkansas Community College, PO Box 7010, El Dorado, Arkansas 71731, USA; e-mail: mconnior@southark.edu.

CROTALUS HORRIDUS **(Timber Rattlesnake)**. USA: GEORGIA: Dodge Co.: 8.8 km NNE Rhine, Wallace Ross Road (32.058699°N, 83.155414°W; NAD83). 22 April 2010. D. Hilliard and R. Little. Verified by Kenneth L. Krysko. UF 16585. New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp).

DELTON HILLIARD, P.O. Box 72, Rhine, Georgia 31077, USA; **RAYMOND LITTLE**, 2523 Mine 18 Road, Strunk, Kentucky 42649, USA; **DIRK J. STEVENSON**, The Orianne Society, Indigo Snake Initiative, 414 Club Drive, Hinesville, Georgia 31313, USA (e-mail: dstevenson@oriannesociety.org)

CROTALUS MITCHELLII PYRRHUS **(Southwestern Speckled Rattlesnake)**. USA: NEVADA: Lincoln Co.: Rainbow Canyon, near Elgin (37.31957°N, 114.4912°W; WGS 84). 20 May 2010. Tim Warfel and Mathew Cage. Verified by Jesse Meik. Brigham Young University (BYU 49910). Campbell and Lamar (2004. The Venomous Reptiles of the Western Hemisphere. Comstock Publishing Associates, Ithaca, New York. 870 pp.) show a large gap in distribution between southwestern Utah and northwestern Arizona in the distribution of *C. mitchellii* and *C. stephensi*. We collected a small female *C. mitchellii* (TL 508 mm; mass 72 g). The nearest specimens are BYU 42847 (59 km SE), MVZ 13102 (138 km W), and CAS 192745 (125 km S) (www.herpnet.org; accessed 27 April 2011). DNA sequencing confirmed species assignment to *C. mitchellii* (J. Meik, pers. comm.). In 1999, two other individuals were observed in this area but were not collected. Although not a new county record, this find represents a substantial range increase and helps fill a major distributional gap. Tissue is available by request from the authors.

BRYAN HAMILTON, 100 Great Basin National Park, Baker Nevada 89311, USA (e-mail: Bryan_Hamilton@nps.gov); **TIM WARFEL,** 4573 South Simms Court, Morrison, Colorado 80465, USA; **MATHEW CAGE**, 13714 Saint Paul Street, Thornton , Colorado 80602, USA.

CROTALUS MOLOSSUS **(Black-tailed Rattlesnake)**. MÉXICO: HIDALGO: Municipality of Chapantongo: Rincón de las Víboras (99.5360°N, 20.2879°W, WGS 84; 2520 m elev.). 28 October 2009. Víctor Vite Silva and Alejandro Ramírez Pérez. Verified by Jesús M. Castillo. Colección Herpetológica, Centro de Investigaciones Biológicas, Universidad Autónoma del Estado de Hidalgo (CH-CIB 2516). First municipality record, extending the range in Hidalgo ca. 46.5 km N from the closest known locality in the Municipality of Tepeji del Río (Ramírez-Bautista et al. 2010. Lista Anotada de los Anfibios y Reptiles del Estado de Hidalgo, México. Universidad Autónoma del Estado de Hidalgo, Pachuca, and CONABIO, México, D.F. 104 pp.). The snake was found in an oak forest. Fieldwork was funded by CONACyT - 95828.

IRENE GOYENECHEA (e-mail: ireneg28@gmail.com), **NALLELY MORALES-CAPELLAN**, and **LEONARDO FERNÁNDEZ-BADILLO**, Centro de Investigaciones Biológicas (CIB), Universidad Autónoma del Estado de Hidalgo, A.P. 1-69 Plaza Juárez, Pachuca, Hidalgo, México.

***CROTALUS MOLOSSUS* (Black-tailed Rattlesnake)**. USA: NEW MEXICO: Valencia Co.: Monte Largo Canyon, Manzano Mts. (34.60445°N, 106.47569°W; NAD83/WGS84; elev. 2090 m). 29 October 2010, 1253 h. Ralph Morris and Ian W. Murray. Verified by J. Tomasz Giermakowski. University of New Mexico Museum of Southwestern Biology (MSB 78227). New county record (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. 431 pp.). The specimen was basking within the shadow of a large rock. Ground surface temperature within the shade was 23°C, ground surface temperature in full sun was 37°C, and shaded air temperature was 29°C. During October 2009, RM found an adult *C. molossus* about 400 m W of this location, but it was not collected. A *C. molossus* (SDNHM 3197) collected in 1930 is listed as being collected in Valencia Co., but the collection locale, near Laguna, New Mexico, is in Cibola Co. This discrepancy results from the 1981 creation of Cibola Co., which occupies a large portion of land that was formerly within Valencia Co.

VILLA, 811 N. 10th Ave, Tucson, Arizona 85705, USA (e-mail: cascabel1985@gmail.com); **PEDRO URIARTE-GARZÓN,** Laboratorio de Recursos Naturales, Escuela de Biología, Universidad de Occidente, Unidad Guasave, Avenida Universidad S/N, Guasave, Sinaloa, México (e-mail: uriartegp@hotmail.com).

***DIADOPHIS PUNCTATUS* (Ring-necked Snake)**. USA: ALABAMA: Fayette Co.: Found under rocks along road cut on Hwy 13 (33.66620°N, 87.65127°W; WGS84/NAD83). 28 March 2011. R. Birkhead. AUM 39448–39449. Franklin Co.: along highway 13/43 north of Russellville (32.832150°N, 85.204133°W; WGS84/NAD83). 29 March 2011. R. Birkhead. AUM 39451–39452. Found in trash pile at abandoned home site. All specimens verified by Craig Guyer. New county records (Mount 1996. The Reptiles and Amphibians of Alabama. University of Alabama Press. xi+347 pp.).

Diadophis punctatus is assumed to occur statewide in Alabama; however, verified records are lacking for some counties. These specimens likely represent intergrades between *D. p. punctatus* and *D. p. stictogenys*. All four have complete neck rings. AUM 39448 and 39452 have belly patterns which anteriorally resemble *D. p. punctatus* but posteriorally resemble *D. p. stictogenys*. In addition, the two Fayette Co. individuals have distinct red tails while the Franklin Co. individuals have only a reddish tint to the tails. Thanks go to Sean Graham for reviewing this note.

***TANTILLA SCHISTOSA* (Red-bellied Earth Centipede Snake; Pequeña Traga-cienpiés)**. HONDURAS: SANTA BÁRBARA: El Cedral (14.916677°N, 88.066884°W, WGS84; 1700–1750 m elev.). 2–3 October 2010. James R. McCranie and Leonardo Valdés Orellana. Verified by Steve W. Gotte. USNM 578918–19. First records for Santa Bárbara, and highest elevation records from Honduras, with the closest known locality being ca. 60 km NNW at El Cusuco, Cortés (McCranie 2011. The Snakes of Honduras. Systematics, Distribution, and Conservation. SSAR Contrib. Herpetol. 26: x + 714 pp.). The snakes were found under logs and in leaf litter on a coffee farm carved from broadleaf cloud forest.

JAMES R. McCRANIE, 10770 SW 164th Street, Miami, Florida 33157–2933, USA (e-mail: jmccrani@bellsouth.net); **LEONARDO VALDÉS ORELLANA**, Gerente General de "Hondufauna," Investigador Privado, Colonia América, Bloque 9, Casa 1806, Comayagüela, MDC, Honduras (e-mail: leovalor@hotmail.com).

***TRIMORPHODON LAMBDA* (Sonoran Lyresnake)**. USA: ARIZONA: Coconino Co.: Marble Canyon and vicinity. Three photographic vouchers deposited in the University of Arizona (UAZ) collection. The first voucher (UAZ 57324-PSV) is from the Echo Cliffs, on Hwy. 89 ca. 2 km E of the junction of Hwys. 89 and 89A (36.63720°N, 111.63054°W; NAD 27; elev. 1636 m). 4 June 2005. B. O'Connor and R. Gassaway. We report a second voucher (UAZ 57325-PSV) from Jackass Canyon and a third voucher (UAZ 57326-PSV) from near confluence of the Paria and Colorado Rivers. All vouchers verified by George Bradley. We also report an unvouchered sighting of a specimen found dead in the bed of Soap Creek, ca. 1.3 km upstream (N) of Hwy. 89A (36.754668°N, 111.75551°W, NAD27; elev. 1275 m) on 13 June 2005 by B. T. La Forest.

Collectively, these represent the first vouchers from Marble Canyon and vicinity (Brennan and Holycross 2006. A Field Guide to Amphibians and Reptiles in Arizona. Arizona Game and Fish Department, Phoenix. 150 pp.). They extend the range of this species 121 river km (75 river miles) upstream along the Colorado River in Grand Canyon from the nearest vouchered locality at the mouth of 75 Mile Canyon (GCNP 22079; Holycross, unpubl. data).

County Records for Reptiles and Amphibians from Hayes County, Nebraska, USA

In Nebraska, USA, many species of reptiles and amphibians reach their distributional limits, and for some species, such limits are well documented (see Lynch 1985). For other species, distributional limits still are not well defined, and records of observation within known ranges are patchy (see Lynch 1985). This lack of records for some species is not a reflection of species abundance, but rather of a lack of intense survey efforts throughout many areas of the state. Few manuscripts have been published in recent decades involving herpetofauna in Nebraska, and until recently, work compiled by Lynch (1985) served as the standalone comprehensive account for their distributions. Within the last year, two field guides (Ballinger et al. 2010; Fogell 2010) have been published which provide an updated synopsis of the life history and distribution of amphibians and reptiles in Nebraska. Our manuscript originally was submitted prior to the completion of both of these recent publications.

Herein, we present detailed accounts of eight county records for Hayes County in southwestern Nebraska that contribute to the aforementioned field guides by providing details on localities of captures. All records were collected during a 24-h survey in July 2009. Voucher specimens with preserved tissues were deposited in Sternberg Museum of Natural History (FHSM), Fort Hays State University, Hays, Kansas. All specimens were verified by Curtis J. Schmidt. All are new county records supported by Lynch (1985). Coordinates were taken with handheld GPS units and are based on North American Datum 1983 (NAD83).

All specimens were collected under authorization of the Nebraska Game and Parks Commission (Scientific and Educational Permit No. 1031).

ANURA – FROGS

***ANAXYRUS COGNATUS* (Great Plains Toad)**. Hayes Co.: 5.8 km W, 5.9 km S Wellfleet (40.6994°N, 100.7978°W). 21 July 2009. Greg D. Wright, Angelina E. Graham, and Keith Geluso. MHP 14697. Fills in distributional gap among Frontier, Chase, and Lincoln counties.

***ANAXYRUS WOODHOUSII* (Woodhouse's Toad)**. Hayes Co.: 5.8 km W, 5.9 km S Wellfleet (40.6994°N, 100.7978°W). 21 July 2009. Greg D. Wright, Angelina E. Graham, and Keith Geluso. MHP 14694.

***LITHOBATES CATESBEIANUS* (American Bullfrog)**. Hayes Co.: Hayes Center State Wildlife Management Area (40.58485°N, 100.92707°W). 22 July 2009. Greg D. Wright, Angelina E. Graham, and Keith Geluso. MHP 14699. Fills a distributional gap between Hitchcock and Lincoln counties.

SQUAMATA – LIZARDS

***PLESTIODON OBSOLETUS* (Great Plains Skink)**. Hayes Co.: 5.8 km W, 5.9 km S Wellfleet (40.6994°N, 100.7978°W). 21 July 2009. Greg D. Wright, Angelina E. Graham, and Keith Geluso. MHP 14701. Fills in distributional gap at northernmost limit in southern Nebraska.

***SCELOPORUS CONSOBRINUS* (Prairie Lizard)**. Hayes Co.: 14.1 km S, 12.8 km W Wellfleet (40.6262°N, 100.88145°W). 22 July 2009. Greg D. Wright, Angelina E. Graham, and Keith Geluso. MHP 14707. Fills in gap among Lincoln, Chase, Hitchcock, and Frontier counties.

SQUAMATA – SNAKES

***COLUBER CONSTRICTOR* (North American Racer)**. Hayes Co.: 16.6 km S, 13.7 km W Wellfleet (40.60403°N, 100.89215°W). 22 July 2009. Keith Geluso, Angelina E. Graham, and Greg D. Wright. MHP 14678. Fills in distributional gap among Lincoln, Chase, and Frontier counties.

New Amphibian and Reptile County Records for the Florida Panhandle

Despite recognition of the Florida panhandle as one of the most biologically rich regions in North America (Blaustein 2008), distribution records apparently do not exist for many amphibian and reptile species in Santa Rosa, Okaloosa, or Walton counties (Ashton and Ashton 1988a, 1988b, 1988c), which make up nearly half of this important area. These counties encompass Eglin Air Force Base (EAFB), an area containing the largest remaining tract of old-growth Longleaf Pine (*Pinus palustris)* forest, an ecosystem renowned for its high diversity and endemism of amphibians and reptiles (Guyer and Bailey 1993). The region has been subject to surveys targeting species of conservation concern; however, most of these remain unpublished reports to state agencies or non-profit organizations. A few recent articles reported species lists or research pertaining to amphibians and reptiles and specify county of capture (Bishop et al. 2006; Enge 2005; Palis 1998). We considered these as formal documentation for a particular species for a county, although museum records may not have been created or specimens vouchered. Here, we present 30 new county records for this region's herpetofauna that have not been previously published elsewhere. All new records are deposited as digital photos (denoted AHAP-D) or specimens in the Auburn University Herpetological collections (AUM), were geo-referenced using Google Earth (WGS 84), and verified by C. Guyer.

NATURAL HISTORY NOTES

CAUDATA — SALAMANDERS

***AMBYSTOMA BARBOURI* (Streamside Salamander). TERRESTRIAL BREEDING SITES.** Adult *Ambystoma barbouri* typically inhabit upland deciduous forests in the vicinity of ephemeral first- and second-order streams with exposed limestone bedrock. These low-order streams have relatively few predatory fish and are typically used as breeding sites by *A. barbouri*, with females laying eggs in a monolayer on the undersurface of flat limestone rocks in streams (Niemiller et al. 2006 Am. Midl. Nat. 156:394–399; Petranka 1998. Salamanders of the United States and Canada. Smithsonian Inst. Press, Washington, DC. 587 pp.). However, *A. barbouri* also breeds in ponds or roadside ditches. In these habitats, females attach eggs to the undersurface of rocks or logs, or attach them singly to vegetation (Petranka 1988, *op. cit.*). Although known to occur in the Central Basin of middle Tennessee since 1998, *A. barbouri* has only recently been reported breeding in first-order streams located in cedar glade habitats (Niemiller et al. 2011. Herpetol. Cons. Biol. 6:135–149). Herein, we report on unusual oviposition sites of *A. barbouri* in cedar glades of middle Tennessee.

Cedar glades are a fragile and imperiled ecosystem characterized by shallow soiled (< 20 cm in depth) treeless openings perched on Ordovician-aged limestone and surrounded by Eastern Red Cedar (*Juniperus virginiana*) or cedar-hardwood forests (Quarterman 1950. Bull. Torrey Botany Club 77:1–9). These openings are often strewn with bedrock fragments of varying size. Because of their association with karst topography, cedar glades lack perennial streams, and ephemeral streams are scant. Rainwater often flows in sheets across the surface of the glades before entering into a subterranean stream or the rare ephemeral first-order surface stream. Because of their unusual hydrology, cedar glades vary from very wet during the winter and spring to very dry during the summer and fall.

On 12 Feb 2011 we found eggs and early stage embryos of *A. barbouri* attached in a monolayer to the undersurface of a rock in the middle of a cedar glade located in Cedars of Lebanon State Forest in Wilson Co., Tennessee, USA (Fig. 1). We initially suspected that an adult confused the sheets of water flowing across the surface of the glades as a stream, and we believed the embryos would soon succumb to desiccation. However, on 25 Feb 2011, we found the egg mass in this glade to be in good condition despite the desiccation of several *A. barbouri* egg masses in a nearby streambed. On 25 March 2011, we again checked the status of the egg mass in the glade and discovered that the eggs had hatched and larvae were swimming in the waters moving across the glade. Furthermore, on 9 April 2011 we found not only late stage embryos attached to the undersurface of rocks in a nearby glade, but we also found newly hatched larvae in small puddles beneath the rocks. Although not visited daily, we now assume that the surface beneath the rocks in the glades remained wet through the late winter and early spring. Small first-order ephemeral streams are located near each of these glades and *A. barbouri* used each stream for breeding during the winter and spring of 2011. We are not certain if the larvae hatching in the glade are able to grow and complete metamorphosis beneath the rocks, or if they can move to a more stable body of water. Thus, we are not certain if our discovery of eggs on land represent ill-fated attempts at reproduction or an alternate breeding site for

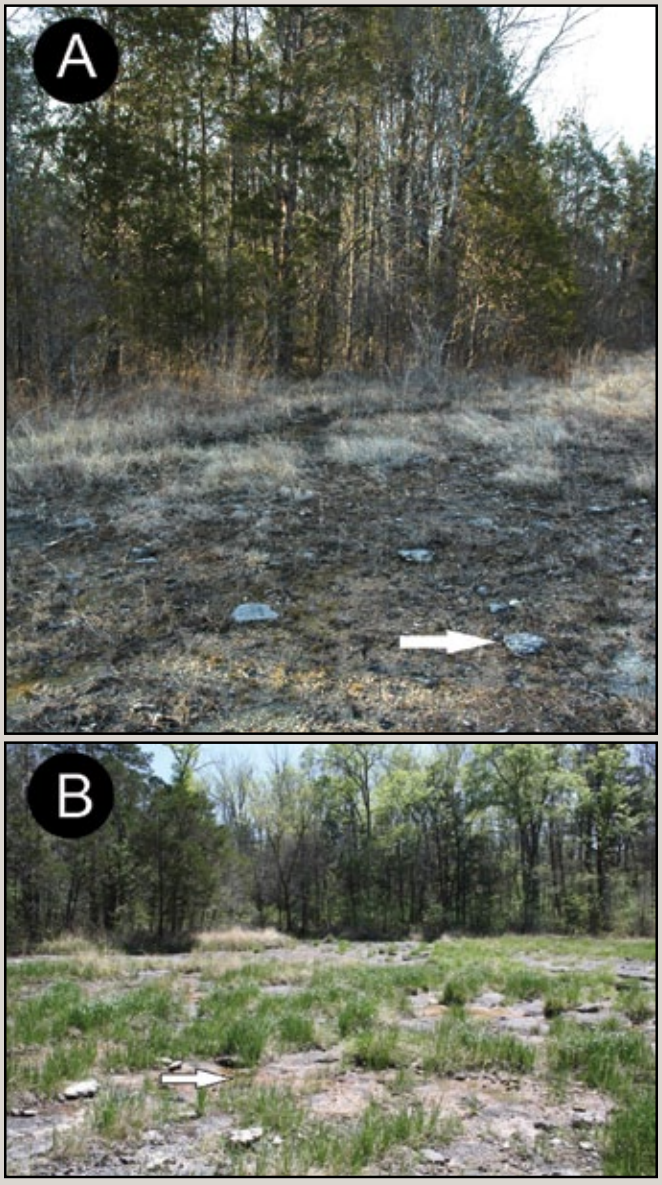

FIG. 1. Breeding sites for the Streamside Salamander (*Ambystoma barbouri*) in cedar glade habitat in middle Tennessee sites. The arrows depict rocks (A) or puddles (B) where egg masses or larvae were found.

A. barbouri in regions where streams are limited and natural ponds non-existent.

EMILY MATTISON (e-mail: erm3c@mtmail.mtsu.edu) and **BRIAN T. MILLER** (e-mail: bmiller@mtsu.edu), Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA.

***AMBYSTOMA TALPOIDEUM* (Mole Salamander). OVIPOSITION MODE AND TIMING.** *Ambystoma talpoideum* breeds in ephemeral, permanent, and semi-permanent depressional wetlands, often exhibiting facultative paedomorphosis in long-hydroperiod ponds (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Inst. Press, Washington, DC. 587 pp.). Depending on regional variation in annual rainfall patterns, peak migration and breeding of terrestrial adults typically occur between November and February throughout most of this species' range; paedomorphic adults are thought to breed as much as six weeks earlier than their terrestrial migrating counterparts (Gibbons and Semlitsch 1991. Guide to the Reptiles and Amphibians of the Savannah River Site. Univ. Georgia Press, Athens, Georgia. 131 pp.; Krenz and Sever 1995. Herpetologica 51:387–393; Patterson 1978. Copeia 1978:649–655; Petranka 1998, *op. cit.*; Scott 1993. Amer. Midl. Nat. 129:397–402; Semlitsch 1985. Copeia 1985:477–489). Oviposition occurs in late winter or early spring shortly after the peak in breeding activity (Semlitsch et al. 1993. J. Anim. Ecol. 62:344–340).

The Mole Salamander displays geographic variation in egg deposition mode, as well as other reproductive traits. Compared to eastern populations, individuals in the western parts of this species' range (Louisiana and Mississippi) deposit eggs in small clumps, with smaller overall clutch sizes and larger hatchlings. In some eastern populations (e.g., South Carolina), females produce larger clutches of smaller hatchlings, on average, and lay eggs singly (Petranka 1998, *op. cit.*). Such variation suggests the potential for genetic differentiation within this species, yet no subspecies are currently recognized (Petranka 1998, *op. cit.*). We provide additional information on the timing and mode of oviposition in *A. talpoideum* to aid in further understanding the geographic scope of variation in this species' reproductive traits.

From 30 March to 3 April 2009, we sampled 15 ponds at St. Marks National Wildlife Refuge, Wakulla Co., Florida, USA, for larval and paedomorphic *A. talpoideum*. Ponds ranged from short hydroperiod, isolated sink-hole ponds in sandhill and Long-leaf Pine (*Pinus palustris*) savanna habitat to longer hydroperiod ponds dominated by cypress (*Taxodium* sp.), blackgum (*Nyssa* sp.), and titi (*Cyrilla* sp. and *Cliftonia* sp.). We sampled each pond with four modified commercial crayfish traps (Johnson and Barichivich 2004. J. Fresh. Ecol. 19:263–269) (2.5 cm mesh, Lee Fisher International, Tampa, Florida, lined with 4-mm Vexar ®). Traps were placed in ≤ 0.5–0.6 m of water, for two trap nights per pond. On 31 March, 1 and 2 April 2009, this area received 33.5, 90.2, and 30 mm of rainfall, (total of 153.7 mm over the 3 d period). This total was the highest 3-d cumulative amount of precipitation that accrued since 1 Sept 2008, which corresponds to the earliest-documented date of migration for this species elsewhere in the Coastal Plain (Semlitsch et al. 1993, *op. cit.*). It also represented 21% of the total rainfall measured at this locality between 1 Sept 2008 and the time of our observations. On 2 April 2009, we captured an adult metamorphosed female *A. talpoideum* (i.e., there was no swollen cloaca typical of breeding males), 50 mm SVL, in one of our crayfish traps placed in 0.6 cm of water (pond W2: 84.4416°N, 30.0489°W; 0.24 ha in area). On 3 April 2009, in a separate, nearby pond (pond W3: 84.4416°N, 30.0489°W; 0.68 ha in area), we found a newly-deposited egg mass (< 24 h old; ≤ Harrison Stage 12, Rugh 1962. Experimental Embryology Techniques and Procedures, 3rd ed. Burgess, Minneapolis, Minnesota. 501 pp.). The mass contained 14 embryos and was attached to the mesh of the trap in the mouth of one of the funnels leading into the trap. These embryos were collected and returned to the laboratory where, upon hatching, we positively identified them as *A. talpoideum*. It is unknown whether these eggs were produced by a metamorphosed adult or by a paedomorph; the latter commonly occur in long hydroperiod ponds at our study site (pers. obs.).

In northwestern Louisiana, Hardy and Raymond (1980. J. Herpetol. 14:327–335) documented immigration by *A. talpoideum* as late as early March, and captured a terrestrial female with oviducal eggs on 2 March 1978 (Hardy and Raymond 1990. Herpetologica 46:371–382). In South Carolina, a few sexually mature females (metamorphosed and paedomorphic combined) may still have enlarged ova and presumably be capable of reproducing as late as March and April (Semlitsch 1985. Oecologia 65:305–313). In Florida, the latest date of new oviposition of which we are aware is 14 February, as reported by Carr (1940. A Contribution to the Herpetology of Florida. Biological Science Series III[1], Univ. Florida, Gainesville, Florida). To our knowledge, our observation of a new egg mass on 3 April is the latest reported date of new oviposition for this species on the Coastal Plain.

In contrast to populations in the Atlantic Coastal Plain, where females deposit eggs singly, our observation also reveals that individuals of *A. talpoideum* in the panhandle region of Florida produce egg masses, similar to populations of this species in western parts of its range (i.e., Mississippi and Louisiana: Raymond and Hardy 1990, *op. cit.*; Semlitsch and Walls 1990. Herpetol. Rev. 21:14–15). This observation suggests that the faunal break between populations that lay eggs singly, versus those that produce egg masses, is much farther east than has been previously reported and closer to the likely geographic point of separation between populations of the two egg-laying modes. Interestingly, a map of frequencies and distributions of mitochondrial DNA (mtDNA) haplotypes reveals extensive population subdivision in this species, with the greatest genetic diversity (i.e., two major haplotype clades abutt each other) occurring in the panhandle of Florida, where we made our observations (Donovan et al. 2000. Evolution 54:1449–1456). Donovan et al.'s results (2000, *op. cit.*) beg for closer scrutiny of egg-laying mode and other reproductive characteristics in populations throughout this species' range, but particularly from areas of the Gulf and Atlantic Coastal Plains that are adjacent to our study area. Such information would be informative for understanding the extent of geographic variation in reproduction and help pinpoint the location of a faunal break between populations of the two egg laying modes in this species.

Fieldwork was supported by the U.S. Geological Survey Amphibian Research and Monitoring Initiative (ARMI). This research was conducted with permits from the Florida Fish and Wildlife Conservation Commission (permit number WX08477), St. Marks National Wildlife Refuge (permit number 41640-2009-09), and the USGS Institutional Animal Use and Care Committee (approval number USGS/FISC 2006-04). We thank Jennifer Staiger and Mike Randall for assistance in the field. This is contribution 386 of the United States Geological Survey's Amphibian Research and Monitoring Initiative (ARMI).

***CRYPTOBRANCHUS ALLEGANIENSIS ALLEGANIENSIS* (Eastern Hellbender) and *DESMOGNATHUS QUADRAMACULATUS* (Black-bellied Salamander). PREDATOR/PREY.** The diet of *Cryptobranchus alleganiensis* consists mostly of crayfish and small fish, although other invertebrates, tadpoles, a toad, aquatic reptiles, and a small mammal have been documented (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington, DC. p. 144).

On 13 April 2011, I observed what likely was a predation event on a large adult *Desmognathus quadramaculatus* (ca. 94 mm SVL) by a juvenile *Cryptobranchus alleganiensis* (ca. 130 mm SVL) during a survey of Eastern Hellbenders in Cooper's Creek Wildlife Management Area within the Chattahoochee National Forest of Union County, Georgia, USA (34.75752°N, 84.08403°W; WGS 84). While turning over a rock in Cooper's Creek with subsequent dip netting, the aforementioned animals were both discovered in the net. Upon transfer from the net into temporary holding boxes, it was discovered that the *D. quadramaculatus* was freshly dead (i.e., not decomposed) and bore recent lacerations consistent with the mandibles and maxillae of the *C. alleganiensis* specimen (Fig. 1B).

It seems likely that the turning of the rock interrupted a predation event, causing the *C. alleganiensis* to release the *D. quadramaculatus*. I believe this is the first recorded occurrence of predation on an adult *D. quadramaculatus* by a *C. alleganiensis* and note that the presumed prey item was nearly as large as the predator. The C. *alleganiensis* was measured and released at the site of capture (Fig. 1A). The specimen of *D. quadramculatus* is deposited at the University of Texas at Arlington (UTA A-61186).

***EURCYEA CHAMBERLAINI* (Chamberlain's Dwarf Salamander). HABITAT.** Since the description of *Eurycea chamberlaini*, little additional natural history information for the species has become available, and distribution records outside of the Carolinas have accumulated slowly (Graham et al. 2009. Herpetol. Rev. 39:476; Jensen et al. 2008. The Amphibians and Reptiles of Georgia. Univ. Georgia Press, Athens. 575 pp.). Only very general information on this species' preferred habitat is currently available (e.g., seepages, streams, or ponds; Harrison and Guttman 2003. Southeast. Nat. 2:159–178), and this may make attempts to locate and study this animal difficult. We developed a general picture of the habitat preferences of *E. chamberlaini* while attempting to determine its distribution in Georgia and Alabama. We have located *E. chamberlaini* at 19 sites, one of which was in the Piedmont physiographic province, and one of which was in the Dougherty Plain region of the Coastal Plain physiographic province (Wharton 1978. The Natural Environments of Georgia. Georgia Geological Survey Bull. 114, Atlanta, Georgia. 227 pp.). The rest of the sites were within the Fall Line Sandhills or Fall Line Red Hills regions of the Coastal Plain physiographic province (Wharton 1978, *op. cit.*). Of these, nine (47%) could be categorized as bay swamps (Wharton 1978, *op. cit.*). Bay swamps contain an overstory of Sweetbay (*Magnolia virginiana*), a dense shrub layer of Doghobble (*Leucothoe axillaris*), greenbrier (*Smilax* spp.) vines, and often thick accumulations of sphagnum moss (Wharton 1978, *op. cit.*). These wetland forests occur in areas associated with first order streams and seepage flow at the base of sandhills, and are especially common in sites along the Fall Line. Three *E. chamberlaini* sites were along the edge of beaver ponds, which often exhibit similar microhabitats, including mats of sphagnum moss. Two sites were along the margins of isolated ephemeral wetlands, and four sites were along first order streams without readily apparent bay swamps, seepage, or sphagnum moss. One individual was found under a log in a xeric longleaf pine-turkey oak forest at least 100 m from the nearest source of water. The specific microhabitat occupied by *E. chamberlaini* was sphagnum moss mats at nine of the sites (47%). At the rest of the sites, salamanders were found either in wet leaf litter, washed-up accumulations of coarse woody debris, or under small logs.

JENSEN**, Georgia Department of Natural Resources, Nongame Conservation Section, 116 Rum Creek Drive, Forsyth, Georgia 31029, USA (e-mail: john.jensen@gadnr.org).

***PLETHODON CINEREUS* (Eastern Red-backed Salamander). COLOR VARIATION.** Two common color forms of *Plethodon cinereus*—redback and leadback—are known to occur through-

out eastern North America (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington, DC. 592 pp.). This species is one of the most common vertebrates in New England, including central Massachusetts, where it is found in both color phases (DeGraaf and Yamasaki 2000. New England Wildlife: Habitat, Natural History, and Distribution. University Press of New England. 496 pp.).

While conducting field work at Cooks Pond, Worcester Co., Massachusetts, USA, on 19 October 2010, a salamander with unusual coloration was found under a decaying log (42.28607°N, 71.85545°W; NAD83). The dorsal surface was dark overall with small blue speckles (Fig. 1A). The anterior ventral surface was a pale cream color with variable speckles becoming darker and blue towards the posterior (Fig. 1B). This adult individual was found less than one meter from another log under which two redback form *P. cinereus* were found. Juvenile salamanders, one with the unusual color form and others with the redback form, were found during a subsequent survey in the same area on 20 October 2010.

We propose this color form is an undocumented variation of the leadback form of *P. cinereus*. The ventral markings of this individual are somewhat similar to both the leadback and redback form of *P. cinereus*; however, the blue speckles on the dorsal surface are a characteristic not found in either the leadback or redback form. The typical leadback form is primarily black or gray on the dorsal surface, while the redback form features a red or orange stripe along the dorsal surface (Conant 1975. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Houghton Mifflin Co., Boston, Massachusetts. 429 pp.). This individual was distinguished from species with similar appearance such as *Ambystoma jeffersonianum* and *Ambystoma laterale* by the number of costal grooves present, overall color pattern, body shape, and geographic range.

FIG. 1. Dorsal (A) and ventral (B) views of the undocumented color variation of *Plethodon cinereus* in Worcester Co., Massachusetts.

Climate change, habitat degradation (Gibbs and Karraker 2006. Cons. Biol. 20[3]:913–917), and predator defense (Venesky and Anthony 2007. Herpetologica 63[4]:450-458) might influence the variable color phases of *P. cinereus*. Whether these processes or genetic mutation are triggering the color variation at Cook's Pond has not been determined. The discovery of adults and juveniles of these two color phases within the same population of *P. cinereus* suggests that interbreeding is occurring, thereby supporting the possibility of genetic mutation as the cause.

We thank Alan Richmond and Joe Choiniere for assistance in identification of the salamander and Terry VanDeWalle for review and comments on this paper.

***PLETHODON CINEREUS* (Eastern Red-backed Salamander). TENACITY AND HOMING.** Homing behavior is the ability or tendency for an individual to return to a particular site or home range after moving or being displaced from that site (Jaeger et al 1993. J. Herpetol. 27:236–239; Ousterhout and Liebgold 2010. Herpetologica 66:269–275). The home range of an individual can be defined by, but is not limited to, the area traveled to forage, mate, and raise offspring (Burt 1943. J. Mammal. 24:346–352). While salamanders might expand and occasionally shift ranges due to external pressures, the home range provides a suitable microhabitat to which the individual may return (Kleeberger and Werner 1982. Copeia 1982:409–415). Certain species of plethodontid salamanders have been known to establish and defend territories under cover objects (e.g., rocks and logs) and the surrounding areas which provide renewable resources, including prey and refugia (reviewed in Mathis 1995. Amphibian Biology 2:633–676; Jaeger 1976. Copeia 1976:686–691; Peterson et al. 2000. Ethology 106:781–794). Although territorial behavior has been well documented in *Plethodon cinereus*, less is known about geographic and phenotypic variation in territorial behavior. For example, most studies of territorial behavior in *P. cinereus* have been conducted on New York and Virginia populations and the effect of color morphology has not been addressed in these studies.

We tested whether striped and erythristic *P. cinereus* from Ohio exhibit homing behavior, a key component of territorial behavior. Between 22 Sept and 3 Nov 2010, we displaced 69 individuals (adults >32 mm SVL; 55 striped, 14 erythristic) 5 m from their original cover object. At least one week passed between displacement dates and recapture dates. Individuals were identified using digital photographs (Nikon D100; Sigma 50mm macro) of their unique dorsal spotting patterns (Anthony et al. 2008. J. Anim. Ecol. 77:646–653). Each cover object was checked at least once, and up to three times after salamanders were displaced.

Of the striped individuals, 12.7% (N = 7) were recaptured under their original cover object. The erythristic morphs had a recapture rate of 14.3% (N = 2). Homing behavior in the red morph has not been documented in previous *P. cinereus* studies and based on these observations the erythristic morph's homing tendency is similar to that of the striped morph. The recapture rate of the striped morph parallels results observed in other plethodontid studies, specifically Jaeger et al. (1993, *op. cit.*) where the

recapture rate of one group was 16.3%. This is the first report of homing behavior in *P. cinereus* from Ohio.

ALYNN M. MARTIN (e-mail: Amartin11@jcu.edu) and **MAGGIE M. HANTAK** (e-mail: Mhantak11@jcu.edu), Department of Biology, John Carroll University, University Heights, Ohio 44118, USA.

***PLETHODON GLUTINOSUS* (Northern Slimy Salamander). ARBOREAL HABITAT USE.** *Plethodon glutinosus* is a common, terrestrial plethodontid salamander found broadly across the eastern United States from New York westward to Illinois and south to Alabama and Georgia. Habitat types for this species vary widely but have been reported primarily as beneath logs, stones, and humus in mature hardwood forests. Refugia in shale banks and cave/bluff systems have also been reported for this species (Beamer and Lannoo 2005. *In* M. Lannoo [ed.], Amphibian Declines: the Conservation Status of United States Species, pp. 808–811. Univ. California Press, Berkeley). *Plethodon glutinosus* is well known for using moist crevices in karst cave or bluff systems and typically exhibits stratification with sympatric Green Salamanders (*Aneides aeneus*). The superior competitive abilities of *A. aeneus* and inferior climbing abilities in *P. glutinosus* have been cited as factors that restrict *P. glutinosus to* lower portions of rock faces (Cliburn and Porter 1986. J. Mississippi Acad. Sci. 31:91–96.). However, *P. glutinosus* has not been shown to exhibit arboreal habitat use, similar to *A. aeneus*, when occurring in bluff systems. Here we report such arboreal habitat use in *P. glutinosus* on two separate occasions from sandstone canyon systems in northern Alabama.

In April 2010, an adult *P. glutinosus* was observed ca. 4 m above ground on a standing, live Canadian Hemlock (*Tsuga canadensis*) within Clear Creek Canyon in Winston Co., Alabama (34.03193°N, 87.37403°W; WGS 84). This individual was using a crevice beneath the outer bark layer of the tree as a refugium, with bark needing to be removed from the tree to gain access to the salamander. On 14 May 2010, a second adult *P. glutinosus* was observed ca. 2.75 m above ground on a standing, live Tulip Poplar (*Liriodendron tulipifer*) within Dismal's Canyon in Franklin Co., Alabama (34.32253°N, 87.78186°W; WGS 84). This individual was observed within a hollow portion of the standing tree and was located directly outside what appeared to be a maintained burrow within the tree. Other encountered salamander species sympatric with *P. glutinosus* at the aforementioned sites include *Eurycea cirrigera, E. guttolineata, Aneides aeneus*, and *Notophthalmus viridescens.*

To our knowledge, these are the first recorded observations of arboreal habitat use in *P. glutinosus*, despite this species' known climbing ability. However, our observations are consistent with other species, such as *A. aeneus*, which have been shown previously to use refugia in standing dead or live trees. Both of the trees observed in our cases were older, mature individuals with large diameters and well-developed crevice systems capable of holding moisture. We observed no salamanders on smaller and/or younger trees within these canyon systems. Both of the aforementioned individuals were also found on the sides of trees facing bluff walls. The sides of trees facing bluff walls within these canyon systems remain consistently wetter than those facing away, providing a near constant source of moisture that may allow for arboreal habitat use in this species. The widespread nature of such habitat use in *P. glutinosus* is questionable and deserves further study, although moisture availability might be a limiting factor in the utilization of arboreal refugia in this species.

Photographic vouchers for the behavioral observations listed above were deposited in the Auburn University Herp Atlas Project - Digital (AHAP-D 301, 302). The observation from Winston Co., Alabama was obtained during research funded by Legacy, Partners in Environmental Education.

SMITH, Box 870206, Department of Biological Sciences, University of Alabama, Tuscaloosa, Alabama 35487, USA (e-mail: whsmith1@crimson.ua.edu); **HEATHER CUNNINGHAM,** Natural History Society of Maryland (e-mail: hcunningham@marylandnature.org); **ALICIA HALL**, McDowell Environmental Center, Nauvoo, Alabama 35578, USA.

***PLETHODON NETTINGI* (Cheat Mountain Salamander). PREDATION.** *Plethodon nettingi*, a federally protected species, is a small-sized terrestrial salamander endemic to the spruce forests of the Allegheny Mountains of West Virginia, USA. To date, no natural predators have been documented, though many are suspected (Petranka 2010. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington D.C. 492 pp.). On 26 May 2010, while surveying a study site in Pendleton Co., West Virginia, USA, we captured a young male *Thamnophis s. sirtalis* (Eastern Gartersnake), ca. 45 cm in total length, under a rock on top of Spruce Mountain (1457 m elev.). *Thamnophis s. sirtalis* is a medium-sized terrestrial snake that is a generalist in nearly all aspects of its natural history, including habitat, diet, distribution, and temperature tolerance. The species is known to ingest earthworms, leeches, slugs, snails, millipedes, isopods, spiders, crayfish, insects, salamanders, frogs, toads, small snakes, nestling birds, mice, fish, and carrion (Ernst and Ernst 2004. Snakes of the United States and Canada. Smithsonian Institution Press, Washington D.C. 680 pp.). Salamander prey consists of 11 genera including *Plethodon*. The *T. s. sirtalis* had an obvious food bolus that was palpated until regurgitation (Fig. 1). The food bolus was a recently eaten adult *P. nettingi*, ca. 45–55 mm in total length. The prey item was doubled over on itself to accommodate the stomach. A juvenile *P. cinereus*, ca. 15–20 mm, was also present but was exceptionally small. This observation,

PHOTO BY KEVIN MESSENGER

FIG. 1. *Thamnophis sirtalis* regurgitating *Plethodon nettingi.*

long considered and expected but never documented, marks another entry on the list of prey items accepted by *T. s. sirtalis*. This observation also marks the first documentation of natural predation on *P. nettingi*.

ANURA — FROGS

BUFO STOMATICUS **(Marbled Toad). DEFENSIVE BEHAVIOR.** *Bufo stomaticus* is widely distributed in the Indian subcontinent (Chanda 2002. Handbook of Indian Amphibians. ZSI, Kolkata, India; Daniel 2002. The Book of Indian Reptiles and Amphibians. BNHS and Oxford Univ. Press, India; Dutta 1992. Amphibians of India and Sri Lanka, Checklist and Bibliography, Odyssey Pub. House, Orissa, India). It is abundant in the vicinity of the Central Aravalli foothills (Sharma et al. 2010. Flora and Fauna 244–248). In spite of its common and wide distribution, little is known about its ecology and behavioral patterns, particularly the defensive behavior when disturbed or attacked by any predator.

On 23 Sept 2010 at 1400 h, during our visit to the Central Aravalli foothills, Rajasthan, India, (26.2666°N, 74.50°E) we observed an interesting defensive behavior when a subadult *Bufo stomaticus* was disturbed. Initially the individual tried to escape but when surrounded from all sides, it suddenly raised its body on its legs and inflated its body (Fig. 1). When the disturbance (a camera) was removed the individual resumed a normal posture, although it resumed the defensive posture when it was again disturbed by the camera.

This research was supported by financial assistance from the Department of Science and Technology, New Delhi, India.

FIG. 1. *Bufo stomaticus* showing defensive behavior.

CYCLORAMPHUS LUTZORUM **(Lutz's Frog). REPRODUCTIVE MODE.** The cycloramphid frog *Cycloramphus lutzorum* has a restricted geographic range in southern Brazil. The call and tadpoles of this endemic species were recently reported by Lima et al. (2010. J. Herpetol. 44:360–371), and karyotypic evolution relationships have been investigated (Noleto et al. *in press*. Zool. Anz.). Nevertheless, the reproductive mode of the species remains uncertain, despite data presented by Lima et al. (2010, *op. cit.*). On 28 Nov 2010 an egg clutch was found at the municipality of Morretes, Parana State, Brazil (25.59055°S, 48.815°W). The eggs were laid at a site lacking daylight, in a moist rock crevice ca. 2 cm high and 50 cm deep under a waterfall along the Brejamirim River. No evidence of clutch attendance was observed. The eggs were counted, measured, and collected for a determination of the state of development. Thirty-six eggs were laid, with a diameter of 0.92 ± 0.04 cm. Eggs were Gosner Stage 18 and tadpoles hatched within 12 days in the lab. These tadpoles matched the description of *C. lutzorum*, which allows inference that the species fits the reproductive mode 19 of Wells (2007. The Ecology and Behavior of Amphibians. Univ. Chicago Press, Chicago, Illinois. 1148 pp.). These data support the notion that *C. lutzorum* is an endemic stream-dwelling species and reinforce the need for conservation of their habitat.

I thank Flora H. M. L. Lima for help in the field.

ANDRÉ MAGNANI XAVIER DE LIMA, Pós Graduação em Ecologia e Conservação, Universidade Federal do Paraná, Curitiba, Brazil. Caixa Postal 19031, CEP: 81531-980; e-mail: andremxlima@uol.com.br.

LEPTODACTYLUS FRAGILIS **(Mexican White-lipped Frog). DIET.** *Leptodactylus fragilis* is a lowland species that occurs from southernmost Texas throughout Middle America to northern and west-central Colombia and northern Venezuela (Heyer et al. 2006. Cat. Amer. Amphib. Rept. 830:1–2). This species is reported to feed on arthropods (Rand and Myers 1990. *In* Gentry [ed.], Four Neotropical Rainforests, pp. 386–409. Yale Univ. Press, New Haven, Connecticut; Savage 2002. The Amphibians and Reptiles of Costa Rica. A Herpetofauna between Two Continents, between Two Seas. Univ. Chicago Press, Chicago, Illinois), but no information exists on food habits of this species. Herein we provided detailed informaton on the diet of *L. fragilis* from Reserva Rio Manso (5.666°N, 74.77417°W; ca 220 m elev.), municipality of Norcasia, Departament of Caldas, Colombia.

We examined the stomach contents extracted by stomach-flushing of 63 individuals of *L. fragilis* sampled by GGD and SEL from 12–20 May 2010, between 1900 and 2200 h, around ponds in pasture lands. We identified each prey item to order or family and measured the length and width of each item to the nearest 0.1 mm using a manual caliper. We estimated prey volume using the formula for a prolate spheroid.

Of the 63 individuals examined, 42 (66.7%) contained prey items. These individuals ranged from 24.4 to 58.4 mm SVL (mean 41.88 ± 7.92). Insects and spiders composed the overall diet. Spiders and beetles were numerically and volumetrically the prey most represented. Numerically, long-toed water beetles (Dryopidae) were the most important prey, followed by orb-web spiders (Araneidae) and wolf spiders (Lycosidae) (Table 1). Volumetrically, lycosids were the most important prey, followed by dryopids and crickets (Gryllidae) (Table 1). Dryopids, araneids, and lycosyds also were common prey in many individuals. The value of dietary niche breadth, measured with the Shannon-Wiener diversity index (H'), was 2.46.

We used the Spearman Rank Correlation for analysis of morphology and diet in the specimens with identifiable prey. A

positive and significant correlation exists between SVL and mouth width (MW) ($r_s = 0.83$, $p < 0.001$). The number of prey ingested was negative and significantly correlated with predator SVL ($r_s = -0.37$, $p < 0.02$) but not with MW ($r_s = -0.30$, $p > 0.05$). The prey volume ingested was positive and significantly correlated with both SVL ($r_s = 0.36$, $p < 0.02$) and MW ($r_s = 0.36$, $p < 0.02$). These results indicate that each individual consumes fewer prey as the SVL increase, but these are voluminous as well (e.g. spiders, dryopids, cockroach, and crickets). In each individual, the average of consumed prey of great size varied between 1 and 2.1 (Table 1).

The consumption of arthropods, mainly insects, by *L. fragilis* is typical due to their insectivorous diet (Rand and Myers 1990, *op. cit.*; Savage 2002, *op. cit*), additionally insects are plentiful and easily found in most terrestrial habitats (Triplehorn and Johnson 2005. Borror and Delong's Introduction to the Study of Insects. Thomson/Brooks Cole, Belmont; Parmelee 1999. Sci. Pap. Nat. Hist. Mus. Univ. Kansas 11:1–59). The notable presence of aquatic insects like the dryopids is important because it associates *L. fragilis* with lentic bodies of water (Savage 2002, *op. cit.*). Unfortunately, we do not know if other *Leptodactylus* associated with lentic waters also prey upon dryopids as the reports only identify prey to order and not family as in our study.

The numeric and volumetric presence of beetles and spiders reported here is not different from the diet of other *Leptodactylus* (Cuevas and Martori 2007. Cuad. Herpetol. 21:7–19; Duré and Kehr 2004. Herpetologica 60:295–303; França et al. 2004. Stud. Neotrop. Faun. Envir. 39:243–248; Maneyro et al. 2004. Iheringia, Sér. Zool. 94:57–61; Rodrigues et al. 2004. Rev. Esp. Herp. 18:19–28; Sanabria et al. 2005. Rev. Peru. Biol. 12:472– 477; Solé et al. 2009. Herpetol. Notes 2:9–15. Teixeira and Vrcibradic 2003. Cuad. Herpetol. 17:111–118; Winter et al. 2007. Herpetol. Rev. 38:324). Ants and termites also have been reported as numerically important prey (n > 22) in *L. bufonis*, *L. latinasus*, *L. ocellatus*, and *L. podicipinus* (Duré and Kehr 2004, *op. cit.*; Maneyro et al. 2004, *op. cit.*; Rodrigues et al. 2004, *op. cit.*; Sanabria et al. 2005, *op. cit.*; Teixeira and Vrcibradic 2003, *op. cit.*), but here ants only were represented by six prey items and termites were not found. The low rates of consumption of other prey types might be as a result of limited availability or they may be patchy in the habitat (Rodrigues et al. 2004, *op. cit.*).

Parmelee (1999. Sci. Pap. Nat. Hist. Mus. Univ. Kansas 11:1–59) suggested that body size and the head width in frogs determine the maximum size of prey consumed. Thus, the ability of gaping in relation to the size of the frog is a limiting factor in the selection of prey (Toft 1981. J. Herpetol. 15:139–144). In this study, the SVL determined the number and volume of prey consumed by *L. fragilis* and the MW determined positively the volume of ingested prey. The above suggests that both the SVL and MW are influencing the type of prey ingested by *L. fragilis*. The wide range of prey types and sizes found in *L. fragilis* indicates the species is a generalist/opportunistic feeder with a "sit-and-wait" strategy for obtaining prey (Taigen et al. 1982. Oecologia 52:49–56), like other *Leptodactylus* species. The previous idea is also corroborated with the high value of dietary niche breadth.

We are grateful to A. M. Jaramillo for providing logistic help in the Reserva Privada Riomanso, and to F. Vallejo and M. Salgado for their help in identifying the prey contents.

GONZÁLEZ-DURAN (e-mail: gustavo.gonzalezdu@gmail.com), **PAUL DAVID ALFONSO GUTIÉRREZ-CÁRDENAS** (e-mail: pdgutierrez2@yahoo.com), and **SERGIO ESCOBAR-LASSO** (e-mail: biosergiobike@gmail.com), Grupo de Ecología y Diversidad de Anfibios y Reptiles (GEDAR), Departamento de Ciencias Biológicas, Universidad de Caldas, Calle 65 # 26-10, A.A. 275, Manizales, Colombia.

***LEPTODACTYLUS MACROSTERNUM* (Miranda's White-lipped Frog). PREDATION.** Amphibians are an important component of the trophic chain in natural ecosystems, being common prey for a variety of vertebrates (fishes, reptiles, birds, and mammals), arthropods (ants, beetles, water bugs, spiders, and crabs), and even carnivorous plants (Duellman and Trueb 1994. Biology of Amphibians. Baltimore and London, The Johns Hopkins Univ. Press; Toledo 2005. Herpetol. Rev. 36:395–400; Toledo et al. 2007. J. Zool. 271:170–177).

Members of the family Belostomidae are predaceous aquatic insects from medium to large size that colonize aquatic habitats in tropical and temperate regions (Lauck and Menke 1961. Ann. Ent. Soc. Amer. 54:644–657).Water bugs are cited by many authors as predators of larval and adult frogs (Martins et al. 1993. Amphibia Reptilia 14:307–309; Eterovick and Sazima 2000. Amphibia-Reptilia 21:439–461; Toledo 2003. Phyllomedusa 2[2]:105–108; Toledo 2005, *op. cit.*), acting to help regulate anuran communities through predation (Duellman and Trueb 1994, *op. cit.*). Here, we report the predation of a juvenile *Leptodactylus macrosternum* by the water bug, *Lethocerus* sp.

On 21 Apr 2011 at 1700 h, in a stream at the Fazenda São Bernardo, municipality of Sambaiba, state of Maranhão, Brazil,

a water bug nymph was observed preying upon an adult *L. macrosternum*. When observed the water bug was grasping the dead frog on its ventral region. When disturbed by our presence the water bug left the prey and dove into the water.

We suggest that such predator/prey interactions could be common when these species are found at the same environment, such as streams and permanent, semi-permanent, or temporary ponds.

LUANA NAZARENO PEREIRA, Pós-graduação em Gerência e Monitoramento Ambiental, Instituto de Ensino Superior do Sul do Maranhão - IESMA, Unidade de Ensino Superior do Sul do Maranhão - UNISULMA, Rua São Pedro S/N, Jardim Cristo Rei CEP 65907-070, Imperatriz, MA, Brazil (e-mail: bio.luana@hotmail.com); **PRISCILLA G. GAMBALE** and **FABRÍCIO HIROIUKI ODA**, Programa de Pós-Graduação em Ecologia de Ambientes Aquáticos Continentais. ***LEPTODACTYLUS TROGLODYTES* (Caçote). LARVAL CANNIBALISM.** Bragg (1964. Herpetologica 20:17–24) reported that cannibalism occurs in the larvae of some frogs; Heyer (1975. Biotropica 7(2):100–111) described cannibalism in *Leptodactylus* larvae. During the night of 17 April 2009 in a permanent pond (ca. 30 × 18 m) in an urban area of the municipality of Natal (S5.838889, W35.205000) state of Rio Grande do Norte, Brazil, we observed the first record of cannibalism in tadpoles of *Leptodactylus troglodytes*. Tadpoles (ca. 12 mm SVL, Gosner Stage 25; Gosner 1960 Hepetologica 16:183–190) being consumed by larger congeners (20 mm SVL Gosner Stage 30) were near the vegetation on the edge of the pond when first observed. They were caught by the larger tadpoles and taken to the bottom of the pond, where parts of the head and abdomen were eaten. Identification of tadpoles was verified by M.N.C. Kokubum.

FREIRE** (e-mail: (elizajuju@ufrnet.br), Laboratório de Herpetologia, Departamento de Botânica, Ecologia e Zoologia, Centro de Biociências, Universidade Federal do Rio Grande do Norte, Campus Universitário, Lagoa Nova, CEP 59072-970, Natal, Rio Grande do Norte, Brazil

***LITHOBATES JOHNI* (Moore's Frog). HABITAT AND MICROHABITAT USE.** Very little is known about the life history of *Lithobates johni* (Blair 1947. Amer. Mus. Nat. Hist. 1353:1–18; Ramírez-Bautista et al. 2010. Lista Anotada de los Anfibios y Reptiles del Estado de Hidalgo, México. Universidad Autónoma del Estado de Hidalgo, CONABIO. 104 pp.). Herein we report habitat and microhabitat use by *L. johni* from the tropical rain forest of Río Blanco (20.24646°N, 98.05434°W; WGS 84; elev. 601 m), Municipality of Huehuetla, Hidalgo, México. *Lithobates johni* are thought to be fully aquatic, however no studies have reported the habitat and microhabitat use of this species. On 15 March 2011, during 2000–2300 h, we found seven (CIB 4114–4120) *L. johni* in tropical rain forest (Fig. 1). These individuals were perched in a cave under a waterfall. Environmental and microhabitat temperatures were 18°C and 16°C. It appears the species prefers non-polluted waters as we did not find individuals in places where the river is polluted.

This study was supported by the projects CONACYT-S 52552-Q and FOMIX-HGO-2008-95828 "Diversidad Biológica del Estado de Hidalgo."

***LITORIA COOLOOLENSIS* (Cooloola Sedge Frog). AMPLEXUS.** In many anurans, males vocalize to attract females but may grasp any female that comes within reach and retain their hold unless displaced by a rival male (Bruning et al. 2010. Biol. Lett. 6:322–324). The male's clasping response may, at times, not discriminate between species, and at the height of breeding, sometimes involves inanimate objects (Brown 1977. J. Herpetol.; Storm 1960. Herpetologica 16:251–259), non-reproductive and reproductive females (Marco and Lizana 2002. Ethol. Ecol. Evol. 14:1–8; Cheong et al. 2008. Anim. Cells Syst. 12:93–96), and even dead frogs (Marco and Lizana 2002. *op. cit.*).

In the Australian subtropical frog *Litoria cooloolensis*, breeding occurs in coastal wetlands in spring, summer, and autumn, where males call from reeds and emergent vegetation over or near water (Meyer et al. 2006. National Recovery Plan for the wallum sedge frog and other wallum-dependent frog species. Queensland Parks and Wildlife Service, Brisbane, report to Department of the Environment and Water Resources, Canberra; pers. obs.). Amplexus is axillary and eggs are laid in clumps in the water amidst vegetation (Meyer et al. 2006, *op. cit.*).

On 3 October 2010 at ca. 1915 h KL observed a male *L. cooloolensis* amplecting a *L. olongburensis* (presumably female) in Great Sandy National Park (Cooloola section), Queensland (Fig. 1). The *L. olongburensis* made no attempt to go to the water to commence egg deposition, nor did it attempt to dislodge or escape from the male. Both species were heard vocalizing during the survey, along with *L. fallax* and *Crinia tinnula*. Environmental air and water temperatures were 19.3°C and 20.1°C. Cloud cover was ca. 50% with no moon, thus a low level of illumination. Humidity was 91.9%, barometric pressure was 1014 hPa. The average pH of the wetland was 3.65 and salinity was 32.76 ppm.

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

FIG. 1. Axillary amplexus between a male *Litoria cooloolensis* and *Litoria olongburensis*.

FIG. 2. Inguinal amplexus between a male *Litoria cooloolensis* and *Litoria rubella*.

A second observation was made on 7 Jan 2011 at ca. 1945 h, where a male *L. cooloolensis* was in amplexus with *L. rubella* (Fig. 2), also in Great Sandy National Park (Cooloola section), Queensland. In this instance, the *L. rubella* was climbing higher up the vegetation and appeared to be attempting to dislodge the unwanted male. Again, both species were heard vocalizing during the survey, along with *L. nasuta, L. tyleri, C. tinnula, Uperoleia fusca, Limnodynastes peroni,* and *Limnodynastes terraereginae*. Environmental air and water temperatures were 23.1°C and 25°C. Cloud cover was 100%, thus a low level of illumination, with some rain that evening. Humidity was 92.8%, barometric pressure was 1001 hPa. The average pH of the wetland was 3.86 and salinity was 21.97 ppm. No release vocalizations were heard from either of the interactions. In both observations the amplected frog was larger than the male, most significantly in *L. rubella*, where the male had to modify its amplexus technique—from axillary to inguinal. Both of these observations were made at the beginning of breeding season in two different wetlands.

In any sexually reproducing species, determining which individual to combine gametes with is a critical determinant of individual fitness and likely to be under strong selection pressure (Andersson 1994. Sexual Selection. Princeton Univ. Press, Princeton, New Jersey). Mate choice is important for successful reproduction and females have been shown to discriminate between species, most commonly on the basis of difference in male vocalizations (Blair 1964. Q. Rev. Biol. 39:334–344). As is apparent from an examination of Figures 1 and 2, the morphological differences between the species are quite clear. Also, the calls of all three species can be readily distinguished, thus female selection is unlikely to have been the cause of these mismatches. Instead, the pairings are likely to have arisen from a male *L. cooloolensis* displaying indiscriminate amplexus, jumping on any frog nearby.

Amplexus confers substantial costs to the amplecting (McLister 2003. Can. J. Zool. 81:388–394) and amplected anuran (Bowcock et al. 2008. Anim. Behav. 75:1571–1579). Thus, it would be beneficial for females (and other males) to immediately terminate 'unwanted' amplexus (Bowcock et al. 2008, *op. cit.*; McLister 2003, *op. cit*). Furthermore, selection should act on males to terminate inappropriate amplexus by rapidly discriminating the sex and reproductive condition of the animal that they have seized (Bowcock et al. 2008, *op. cit.*).

The females may not have been receiving the correct chemical cues to proceed with breeding as neither was observed to commence with egg deposition. However some mechanisms for repelling unwanted suitors have been observed in other species. These include release vocalizations (Leary 2001. Anim. Behav. 61:431–438), inflating the body (Bruning et al. 2010, *op. cit.*), and laying fewer eggs when paired with heterospecific males (Hettyey 2009. Anim. Behav. 78:1365–1372).

KL has been surveying 16 Wallum Frog breeding sites over two years (approx. 500 survey hours) and has never observed a pair of *L. cooloolensis* or *L. olongburensis* in amplexus. This suggests that observations of such behavior might be rare, and might be quickly followed by egg deposition. The two observations discussed here lead to questions of hybridization between *L. cooloolensis* and *L. olongburensis,* as they share similar morphology, breeding habitat, breeding seasons, and calling perch sites. Further studies examining the viability of hybrid offspring and identifying the cause of matings between different species in hybrid populations would add to our understanding of hybridization and mate recognition in amphibians.

KATRIN LOWE (e-mail: k.lowe@griffith.edu.au) and **JEAN-MARC HERO** (e-mail: m.hero@griffith.edu.au), Environmental Futures Centre, School of Environment, Griffith Univ., Parklands Drive, Gold Coast Campus, Queensland 4222, Australia.

***MEGOPHRYS KOBAYASHII* (Montane Horned Frog). ATYPICAL HABITAT AND MAXIMUM SIZE.** *Megophrys kobayashii* is endemic to the mountainous western Sabah, Bornean Malaysia between 1230–1675 m elev. (Inger and Stuebing 2005. A Field Guide to the Frogs of Borneo. 2nd ed. Natural History Publications [Borneo] Sdn. Bhd. Kota Kinabalu. 201 pp.; Frost 2010. Amphibian Species of the World: an Online Reference. Version 5.4 [8 April 2010]. Electronic database accessible at http://research.amnh.org/vz/herpetology/amphibia. Amer. Mus. Nat. Hist., New York. Accessed 1 February 2011), and is listed as Near Threatened in the 2010 IUCN Red List of Threatened Species (Inger et al. 2004. *In* IUCN 2010. IUCN Red List of Threatened Species. Version 2010.4. <www.iucnredlist.org>. Accessed 1 Feb 2011). The species has been reported to dwell in leaf litter of primary montane forests with small rocky-bottomed streams for breeding; maximum size reported to be SVL 109 mm (Inger and Stuebing 2005, *op. cit.*; Malkmus et al. 2002. Amphibians and Reptiles of Mount Kinabalu [North Borneo]. A.R.G. Gantner Verlag K.G. Ruggell. 424 pp.).

On 8 Dec 2010 at 1915 h, a gravid female *M. kobayashii* was found at the foot of a leaf-littered hill in the compound of Haleluyah Retreat Centre (6°N, 116.536°E; 1518 m elev.), Bundu Tuhan, Ranau District, West Coast Division, Sabah, Bornean Malaysia. Air temperature was 19.9°C, and relative humidity was 75.7%. The individual was found ca. 25 m from an artificial pond. However, the compound lacks a stream or brook thought to be necessary for breeding in *M. kobayashii* (Inger and Stuebing 2005, *op. cit.*; Malkmus et al. 2002, *op. cit.*). It is possible that an attempted escape from a predator might explain the presence of *M. kobayashii* in the compound although no predators were observed; additionally the species normally lives in permanent colonies (Malkmus et al. 2002, *op. cit.*). This observation suggests that *M. kobayashii* might utilize a wider variety of habitats than currently known.

This individual was 118 mm SVL and 151 g, and thus a new maximum size for *M. kobayashii*. Measurements were taken with a standard metric tape and an electronic balance. The individual was photographed *ex-situ* indoors and released on site the following day.

We thank Haleluyah Retreat Centre for permission to sample and lodgings support, as well as the Institute for Tropical Biology and Conservation, Universiti Malaysia Sabah for support.

***PLEURODEMA TUCUMANUM*. PREDATION.** Water bugs (Belostomatidae) are well known to prey on anuran larvae (Giaretta and Menin 2004. J. Nat. Hist. 38:1711–1722; Hinshaw and Sullivan 1990. J. Herpetol. 24:196–197; Kher and Schnack 1991. Alytes 9:61–69; Menin et al. 2005. Phyllomedusa 4(1):39–47) and adults (Bastos et al. 1994. Herpetol. Rev. 25:81; Haddad and Bastos 1997. Amphibia-Reptilia 18:295–298; Mijares-Urrutia et al. 1997. Herpetol. Rev. 28:84; Toledo 2003. Phyllomedusa 2[2]:105–108). Water bugs eat more frogs than invertebrates because anurans are better food items from an energetic viewpoint (Hidai and Hidaka 2002. Ecol. Res. 17:655–661); they use their piercing-sucking mouthparts to eat them (Lopez et al. 1998. Rev. Nica. Entomol. 46:1–5).

Herein we report predation of a juvenile *Pleurodema tucumanum* by the water bug *Belostoma discretum*. This observation took place during the night of 9 April 2009 in the vicinity of the Rio Claro (32.613°S, 66.139°W), near San Francisco, Ayacucho, San Luis 5570, Argentina, in a large pool enclosed by rocks at the river's edge. A juvenile *P. tucumanum* (19.6 mm SVL) was observed floating on the surface of the pool (no deeper than 0.2 m), with a *B. discretum* (24.8 mm long) attached to its abdomen. The water bug was holding the frog with its forelegs while piercing the frog's left hindlimb with its proboscis. At regular intervals the water bug swam with apparent difficulty carrying the frog to the bottom of the pool, where it rested for an instant before emerging for air and repeating these actions.

These individuals were photographed, collected, and preserved in 70% ethyl alcohol. The *B. discretum* was deposited in the UNSL Entomological Collection and the *P. tucumanum* (CH-UNSL 0429) in the Herpetological Collection of Universidad Nacional de San Luis. This is the first record of *B. discretum* preying on juvenile *P. tucumanum*.

This work was supported by PROICO 9401 UNSL. We are grateful to A. C. Armúa de Reyes for identifying the water bug and L. Alcalde for assistance. We thank C. Morgan for the English translation.

***POLYPEDATES LEUCOMYSTAX* (Java Whipping Frog). COMMUNAL NESTING.** Communal egg-laying is widespread in amphibians yet the exact reasons for it remain unclear (Doody et al. 2009. Quart. Rev. Biol. 84[3]:229–252). In nest building species, there appears to be plasticity within a population for nesting communally versus individually (Agostini et al. 2007. Herpetol. Rev. 38:441; Zina 2006. Amphibia-Reptilia 27:148–150), indicating that perhaps in certain contexts one method is more advantageous than another. Here we report communal nesting activity in *Polypedates leucomystax* at the Xishuangbanna Tropical Botanic Garden, Xishuangbanna Prefecture, Yunnan Province, China, during one of the driest rainy seasons on record (Qiu 2010. Nature 465[13]:142–143).

In weekly breeding site surveys, we recorded instances of communal nesting on 9 July and 12 Aug 2009. On 9 July, we encountered two large foam nests, the larger nest measuring ca. 59 cm × 48 cm, and the smaller one measuring 62 cm × 39 cm. In addition, at the same site but several meters away from the larger nest, we observed a single female actively mating with 4 males as has been recorded in this species before (Feng and Narins1991. Naturwissenschaften 78:362–364), however, when we approached the group, the males dispersed. On 12 Aug we recorded an additional large nest at the same site as the first two, and slightly smaller in size measuring 32 cm × 46 cm. On both dates we also observed multiple individual nests at the same site (see Fig. 1 for comparison of nest sizes). These communal nests are no doubt the product of multiple females ovipositing in the same location, but since we did not observe it, we do not know if oviposition happened simultaneously or separately.

FIG. 1. On left, the larger of two communal nests of *Polypedates leucomystax* observed on the night of 9 July 2009. On the right, an average-sized individual female nest. The 50 yuan note measures 15 cm x 7 cm.

In the three years of conducting breeding site surveys (2008–2010), these are the only instances of communal nesting we encountered for any species. Both dates that we recorded communal nesting were after major rain events (>50 mm rain) following significant dry spells (25–28 d) where no standing water accumulated. It is possible that since these populations rely heavily on ephemeral pools for reproduction there is high competition for the spots that retain water longest.

We thank Xishuangbanna Tropical Botanic Garden for access to breeding areas. Funding was provided by Fulbright and NSF DGE-0549369.

JOCELYN E. BEHM, 430 Lincoln Drive, Madison, Wisconsin 53706, USA (e-mail: (jebehm@wisc.edu); **BRENNA KNAEBE**, 4026 Euclid Ave, Madison, Wisconsin 53711, USA (e-mail: knaebe@uwalumni.com; **VIVIAN WING KAN FU**, 14/F, Ruby Commercial Bldg., 480 Nathan Rd., Yau Ma Tei, Kln., Hong Kong; **DEVIN EDMONDS**, 5101 Golden Leaf Trl. Madison, Wisconsin 53704, USA.

***PRISTIMANTIS ACHATINUS* (Cachabi Robber Frog). PARENTAL CARE AND CLUTCH SIZE.** *Pristimantis* is the largest clade of frogs in the world with nearly 445 species, distributed mainly in northwestern South America (Amphibiaweb 2011.. [web application]. Berkeley, California. Available: http://amphibiaweb.org/; accessed 27 May 2011; Hedges et al. 2008. Zootaxa 1737:1–182). These frogs have terrestrial eggs and embryos undergo direct development (Hedges et al. 2008, *op. cit.*). To date, there are published data on clutch size, nest type, and parental care in 10 species of *Pristimantis*: *P. affinis*, *P. buccinator*, *P. caryophyllaceus*, *P. lymani*, *P. nicefori*, *P. percultus*, *P. racemus*, *P. simoterus*, *P. terraebolivaris,* and *P. verecundus* (Carrillo 2007. Herpetol. Rev. 38:183; Heatwole 1963. Carib. J. Sci. 3:17–23; Lynch and Duellman 1997. Univ. Kansas. Nat. Mus. Spec. Publ. 23:1–236; Lynch et al. 1996. Caldasia 18:329–342; Myers 1969. Am. Mus. Novit. 2396:1–52; Townsend 1996. *In* Powell and Henderson. Contributions to West Indian Herpetology, a Tribute to Albert Schwartz, pp. 229–239. SSAR Contrib. Herpetol. Vol. 12. Ithaca, New York; Vargas-S. and Castro-H. 1999. Rev. Acad. Colomb. Cienc. 23:407–410). Herein we provided the first data on nest site, clutch size, and parental care in *P. achatinus* from a premontane humid forest in the Central Andes of Colombia. This species occurs in Panama, Colombia, and Ecuador, at altitudes of 0–2330 m (Frost 2011. Amphibian Species of the World: an Online Reference. Version 5.5 [31 Jan 2011]. Electronic database accessible at http://research.amnh.org/vz/herpetology/amphibia/. American Museum of Natural History, New York; accessed 27 May 2011).

On 25 May 2011, we found an adult female *P. achatinus* (37.9 mm SVL) sitting on a clutch of 38 eggs (Fig. 1A) at Ecoparque Los Alcázares Arenillo, municipality of Manizales, Department of Caldas, Colombia (5.067°N, 75.533°W, 1730–1960 m elev.). Both the female and the egg mass were in a shallow depression (ca. 25 mm deep) on the ground beneath leaf litter, next to small shrubs. At the time of finding the nest, the female was completely covering the eggs with the body and head, so that the eggs were not visible, which could be evidence of parental care. However, minutes after being disturbed the frog moved, allowing us to see the eggs (Fig. 1A). The eggs were spherical with yellowish cream yolk and clustered in a grape bunch although not connected by a jelly or foam matrix (Fig. 1B). We examined 10 eggs that ranged from 4.1–4.6 mm diameter (mean 4.46 ± 0.17) and we estimated them to be approximately early stage 5 of development based on the limb buds elongate and attached to trunk, forelimbs round to ovoid, and hindlimbs round to ovoid-elongate, eyes prominent but unpigmented, and gill buds present (Townsend Stewart 1985. Copeia 1985:423–436).

Although there is a widespread lack of data on parental care *Pristimantis*, the available data and this report suggest that females attend nests. Based on the data summarized by Wells (2007. The Ecology and Behavior of Amphibians. University

FIG. 1. A) Egg attendance by female *Pristimantis achatinus* in the Ecoparque Los Alcázares Arenillo, Manizales, Colombia. B) *Pristimantis achatinus* egg clutch in a shallow depression in the soil.

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

of Chicago Press, Chicago, Illinois) and others (Rodríguez and Alonso 2009. Herpetol. Rev. 40:204; Ryan 2005. Herpetol. Rev. 36:234–236; Whitfield et al. 2008. Herpetol. Rev. 39:76), in *Craugastor* and *Strabomantis* the females performed parental care, whereas in *Diasporus* it is the male, and in *Eleutherodactylus* the behavior is accomplished by females, males, or either parent.

We thank students M. Salazar, M. Duque and A. Vásquez from Instituto para la Ciencia, for their assistance in the field.

***RANA BOYLII* (Foothill Yellow-legged Frog). REPRODUCTION.** *Rana boylii* is an obligate lotic breeding ranid ranging from southern California north into southwestern Oregon, USA. *Rana boylii* breeds in spring (March–June) as winter flows subside, exhibits high breeding-site fidelity, and oviposition typically occurs on cobbles and boulders along river and stream margins in microhabitats with less than ambient flows (Fellers 2005. *In* Lannoo et al. [eds.], Amphibian Declines: The Conservation Status of United States Species, pp. 534–536. Univ. California Press, Berkeley). This species is listed as Near Threatened by the IUCN (Santos-Barrera et al. 2004. *In* IUCN 2010. IUCN Red List of Threatened Species. www.iucnredlist.org; accessed 10 April 2011) and has been a California Species of Special Concern since 1994 (Jennings and Hayes 1994. Amphibian and Reptile Species of Special Concern in California. California Dept. of Fish and Game, Rancho Cordova. 254 pp.). Annual census of egg masses is an effective means for quantifying population trends in frog species that lay one clutch per year at conspicuous oviposition sites (Crouch and Patton 2000. Wildl. Soc. Bull. 28:895–901). However, historical data on annual reproductive output for *R. boylii* populations throughout the range are limited, making it difficult to adequately assess the severity of population declines. Here we report the highest known density of egg masses for this species.

On 31 May 2009 (1100–1630 h) we conducted a visual encounter survey along a 2.25 km segment of the Mad River, in Humboldt Co., California, USA (40.8292°N, 123.9423°W, elev. 45 m) to quantify *R. boylii* egg masses. The sampled river segment is a low gradient meandering channel, with abundant gravel and cobble substrates, and adjacent uplands principally comprised of third growth Coast Redwood (*Sequoia sempervirens*) timberlands. We timed this survey to coincide with the final descending limb of the hydrograph and to be at the apparent peak of the breeding season. The peak of the 2009 breeding season was determined based on two visits to a known breeding site located downstream (7 km) from the sample reach. The mean surface water discharge of the river was 258 cfs (U.S. Geological Survey, Surface Water data for California: USGS Surface-Water Daily Statistics. http://waterdata.usgs.gov/ca/nwis/ dvstat?. Accessed 10 April 2011). We counted a total of 728 *R. boylii* egg masses for a resulting density of 323.5 egg masses km^{-1}. Forty-one egg masses (5.6% of the total counted) we observed were stranded on the river bank and presumably desiccated prior to hatching. The density we report here is 183% the maximum reported elsewhere. The highest reported density for *R. boylii* egg masses among 27 other rivers or streams is 176.9 egg masses km^{-1}, however the average among these sites is 16 egg masses km^{-1} (Kupferberg et al., *in review*). We believe that our finding on the annual reproductive output for *R. boylii* is a useful baseline for describing the population-level reproductive potential for the species and for comparison with other populations in similar river systems.

RYAN M. BOURQUE, Green Diamond Resource Company, 900 Riverside Road, Korbel, California 95550, USA (e-mail: rbourque@greendiamond.com); **JAMES B. BETTASO**, U.S. Fish and Wildlife Service, 1655 Heindon Rd., Arcata, California 95521, USA.

***RANA BOYLII* (Foothill Yellow-legged Frog) and *ANAXYRUS BOREAS* (Western Toad). INTERSPECIFIC AMPLEXUS.** On 14 June 2010, during egg mass surveys on the South Fork Trinity River, Humboldt Co., northwestern California, USA, a male *Rana boylii* was observed in amplexus with a female *Anaxyrus boreas* at 1455 h (Fig. 1). Yearly surveys for egg masses and egg strings have been conducted since 2004, with numerous encounters of intraspecific amplexus being seen every year. In previous reports for Western Toads in interspecific amplexus, Brodie (1968. Herpetologica 24:86) witnessed a male Cascades Frog (*Rana cascadae*) in amplexus with a female Western Toad and Brown (1977. J. Herpetol. 11:92–94) reported a male Western Toad in amplexus with a female Northern Red-legged Frog (*Rana aurora*). It has been reported that non-native American Bullfrogs (*Lithobates catesbeianus*) that enter amplexus with native anurans could create reproductive interference (D'Amore et al. 2009. Herpetol. Cons. Biol. 4[3]:325–330; Pearl et al. 2005. Amer. Midl. Nat. 154:126–134) and this would be a case of heterospecific mating attempt (Groning and Hochkirch 2008. Quart. Rev. Biol. 83:257–282). This is the first observation of amplexus between a native ranid and a native bufonid in California and of these species pairing.

FIG. 1. Male *Rana boylii* in amplexus with female *Anaxyrus boreas* in the South Fork Trinity River, Humboldt Co., California.

***RANA YAVAPAIENSIS* (Lowland Leopard Frog). LARVAL CANNIBALISM.** *Rana yavapaiensis* is known to oviposit primarily in

late winter-spring, with a much smaller pulse of oviposition in early fall (Sartorius and Rosen 2000. Southwest. Nat. 45:267–273) and large tadpoles sometimes overwinter (Collins and Lewis 1979. Southwest. Nat. 24:371–373). This situation occurred during winter 2005–6 in my semi-natural, urban backyard pond (3 × 4 m, 0.4 m deep), which has had a self-sustaining frog population derived from three southeastern Arizona populations for several years. In monitoring the 4th of eight egg masses deposited in February–early March 2006, I briefly noted about 5–6 large tadpoles (5.5–7.5 cm LOA) from a single September 2005 clutch active around and under the egg mass, which had just begun to hatch, on 5 March. On 7 March closer inspection of the 5th egg mass, which was estimated to be at developmental stages 16–19 and predicted to be 50% hatched on 9 March, revealed about 12–18 large tadpoles (of an estimated 48+ present in the pond) active under, around, and on the egg mass. Tadpoles were swimming lazily, pushing into the mass with actively moving mouthparts, and, in at least one case observed to swallow a dislodged embryo. Water was 11 cm deep at the mass, which was about 8 cm diameter, and temperature was 17°C (range 13–20°C over 24 h). The mass originally contained an estimated 1100 eggs based on previous counts of hatchlings in other clutches of similar size; 30 h later there were only 18 developing ova remaining, the egg mass was reduced in size but not dissociating as expected post-hatching, and no hatchlings were observed near the egg mass site, as would normally be seen. Other egg masses appeared to be less affected in proportion to the depth of water column below them, with hatchlings seen around all of them, and there was less activity of large tadpoles near them. However, the 8th and deepest-water egg mass, which hatched last (15 March), attracted about 15 large tadpoles on the bottom where a cone of detaching hatchlings from it would likely fall. Five of these tadpoles transferred to a screened-in observation tray with 10 hatchlings apparently consumed four hatchlings in a 24-h period.

The frog and tadpole densities involved here are similar to the highest *R. yavapaiensis* abundances I have seen in Arizona and Sonora during 1983–2005, and the only other vertebrate in the pond is the Gila Topminnow (*Poeciliopsis occidentalis*). An accumulating literature on oophagy, larvivory, and cannibalism in tadpoles (Gunzberger and Travis 2005. J. Herpetol. 39:457–571), and their occurrence in species with generalized tadpoles such as in this species and the American Bullfrog (*R. catesbeiana*; Kiesecker and Blaustein 1997. Ecology 78:1752–1760), may support suggestions in McDiarmid and Altig (1999. Tadpoles: the Biology of Amphibian Larvae, pp. 218, 246. Univ. Chicago Press, Chicago, Illinois) that these may be widespread and ecologically important phenomena.

PHILIP C. ROSEN, School of Natural Resources and the Environment, University of Arizona, Tucson, Arizona 85721, USA; e-mail: pcrosen@u.arizona.edu.

***RHACOPHORUS MARGARITIFER* (Java Flying Frog). DEFENSIVE BEHAVIOR.** *Rhacophorus margaritifer* is endemic to the island of Java in Indonesia. This species has received little treatment in the literature and many aspects of its natural history remain unknown. A recent monograph examining the genus *Rhacophorus* (Harvey et al. 2002. Herpetol. Monog. 16:46–92) described morphological diversity in *R. margaritifer* and briefly mentioned an *in situ* Unken reflex exhibited by one of the specimens examined. The individual described herein (along with several other *R. margaritifer*) was collected at the Taman Safari Park, in Cisurua-Bogor, West Java (06.716667°S, 106.95000°E; WGS 84), 1300 m elev., on 13 May 1996 and is deposited in the vertebrate collection of the University of Texas at Arlington (UTA A-54009). This and another specimen (UTA A-54010) were found active on low bushes, 1.4–1.8 m above the edge of a rocky stream flowing through primary forest on a warm night, ca. 18°C and 1945 h. The photographs taken of this reflex (Fig. 1), enable us to describe the behavior in detail. The behavior was expressed the day after capture while trying to photograph the specimen. This behavior involved the *R. margaritifer* covering its eyes with its hands and slightly arching its back (Fig. 1; bottom). These actions are consistent with those reported to occur during the Unken reflex of several anuran species (Stebbins and Cohen 1995. A Natural History of Amphibians. Princeton Univ. Press Princeton, New Jersey. 315 pp.). Interestingly, a similar reflex was reported from *R. feae* (Duong et al. 2010 Herpetol. Rev. 41:342). The behavior is also known to occur in a closely related rhacophorid *Nyctixalus pictus* (Das et al. 2004. Herpetol. Rev. 35:363–374). As such, a thorough survey across rhacophorids might provide valuable insight into the prevalence and modes of defensive behavior in this group. Collection and exportation were conducted with Bogor Zoological Museum permits (14/SI/MZB/VI/1996).

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

***RHINELLA CRUCIFER* (Striped Toad) and *RHINELLA JIMI*. HETEROSPECIFIC AMPLEXUS.** Most members of the family Bufonidae are regarded as having an explosive breeding pattern (Wells 2007. The Ecology and Behavior of Amphibians, Univ. Chicago Press, Chicago, Illinois. 1148 pp.), where after the first heavy rains of the season males begin calling and actively searching for females. During this reproductive frenzy males may commit mistakes and try to amplex with male conspecifics, heterospecifics, other vertebrates, or even inanimate objects of adequate size (Marco and Lizana 2002. Ethol. Ecol. Evol. 14:1–8; Wells 2007, *op. cit.*).

On 25 Nov 2010, at Parque das Trilhas, municipality of Guaramiranga, State of Ceará, northeastern Brazil (4.266°S, 38.916°W; 865 m elev.), we observed males of *Rhinella crucifer* and *R. jimi* in amplexus with heterospecifics. These observations took place in an artificial water body at ca. 2000 h, when only these two species were heard calling (*R. crucifer*, N = 5; *R. jimi*, N > 50). One *R. crucifer* was found in amplexus with a female *R. jimi*. When first seen, the pair was already in an axillary amplexus position in which they remained for 10 min. Towards the end of this time period the female began to raise the rear part of her body and direct her snout towards the ground in an attempt to be released until it finally succeeded (the behavior was videotaped and is available from LB upon request). Fifteen minutes after this observation, a male *R. jimi* was found in amplexus with *Leptodactylus vastus* (sex undetermined), which made no apparent attempt to dislodge the male. When approached by LB, the *L. vastus* jumped into the deeper part of the lake taking with it the amplectant male.

Haddad et al. (1990. Rev. Bras. Biol. 50:739–744) reported a *R. crucifer* × *R. icterica* hybrid. Considering that *R. jimi* is closely related to *R. icterica* such mistakes might be relatively common in areas where these species occur in sympatry with *R. crucifer*. According to Sinovas (2009. Herpetol. Rev. 40:199) the cost of amplexing a reproductively inadequate specimen is probably outweighed by the benefits of being the first to encounter an appropriate partner, as this behavior has not been selected against. Machado and Bernarde (2011. Herpetol. Notes 4:167–169) reported heterospecific amplexus involving *Rhaebo guttatus* and *Rhinella marina* in the Amazon. Although most records of heterospecific amplexus have been made in temperate environments (Wells 2007, *op. cit.*), these recent observations from tropical areas suggest that such behavior is found in Bufonidae worldwide.

We thank H. Varella and S. Brito (Parque das Trilhas) for allowing access to the area and for logistic support, D. Hissa for field assistance, P. S. Bernarde for revising the manuscript, and the Fundação Cearense do Desenvolvimento Científico e Tecnológico (FUNCAP) for the fellowship granted to LB.

LUCAS BEZERRA (e-mail: lucasmb15@yahoo.com) and **PAULO CASCON** (e-mail: pc@ufc.br), Programa de Pós Graduação em Ecologia e Recursos Naturais da Universidade Federal do Ceará, Laboratório de Zoologia Experimental, Universidade Federal do Ceará, Campus do Pici, CEP 60455-760, Fortaleza, Ceará, Brazil.

***RHINELLA JIMI* (Cururu Toad). ECTOPARASITISM.** *Rhinella jimi* is a bufonid that occurs throughout northeastern Brazil where it inhabits forests along the Atlantic coast as well as open formations of Caatinga. It is the only species in the genus that inhabits the Fernando de Noranha archipelago (Stevaux 2002. Rev. Bras. Zool. 19[1]:235–242; Toledo and Ribeiro 2010. EcoHealth 6:351–357). Here we report parasitism of *R. jimi* by the tick *Amblyomma rotundatum* (Ixodidae).

On 19 Dec 2010 at 2114 h at the Unidade de Conservação Refúgio de Vida Silvestre Mata do Junco, municipality of Capela, State of Sergipe, Brazil (10.291037ºS, 36.58370ºW, 120 m elev. SAD 69), an adult R. jimi (167.5 mm SVL) was observed parasitized by five ticks of the species Amblyomma rotundatum (Fig. 1A). Three of the ticks were fixed on the posterior part of the toad's dorsum (Fig. 1B), and the other two ticks were located in the inguinal region between the folds of the rear legs. Amblyomma rotundatum, known as Toad Tick, has been reported to parasitize a variety of amphibians (Ahid et al. 2009. Rev. Bras. Zool. 11[2]:153–158; Guglielmone and Nava 2010. Zootaxa 2541:27–49; Rodrigues et al. 2010. Rev. Bras. Parasitol. 19[3]:174–178; Woehl 2002. Rev. Bras. Zool. 19[2]:329–333). Amblyomma rotundatum is native to Central and South America, but has been found in North America, where it was introduced via Rhinella marinus (Boffy and Santos 2010. Herpetol. Rev. 41:342–343; Rodrigues et. al. 2010, *op. cit.*).

The ticks are deposited in Coleção do Laboratório de Entomologia (ENTUFS 00001) and the toad in Coleção Herpetológica da Universidade Federal de Sergipe (CHUFS C 1248). This is the first report of parasitism of *R. jimi* by *A. rotundatum* and the first report of ticks parasitizing amphibians in the State of Sergipe.

We thank L. G. G. Borges for review of the manuscript and M. B. Labruna for the identification of the ticks. The Secretary of Environment and Hydrological Resources (SEMARH/S) for the collecting permit, and the Federal University of Sergipe for logistical support.

FIG. 1. A) Adult *Rhinella jimi* (167.5 mm SVL) parasitized by the tick, *Amblyomma rotundatum*. B) *Amblyomma rotundatum* attached to the dorsum of *R. jimi*.

***RHINELLA MARINA* (Cane Toad). DIET.** Although the invasive Cane Toad's diet in Australia consists primarily of insects, vertebrates are occasionally ingested (Lever 2001. The Cane Toad. Westbury, Otley). Herein we report on predation by the Cane Toad on a nestling bird. As part of a larger study, LP collected a large female *Rhinella marina* (SUL 95 cm) on 1 Dec 2008, from the grounds of Walkabout Palms Caravan Park, Townsville, Queensland (19.3166°S, 146.8°E; WGS 84). Examination of the stomach contents from this specimen revealed one large beetle, and one nestling bird (Fig. 1). The bird was a House Sparrow, *Passer domesticus*, also an invasive species in Australia. These birds are cavity nesters, therefore it is likely the nestling somehow fell from the nest, or perhaps fledged prematurely. *Passer domesticus* nestlings fledge around 14 days of age (Lowther et al. 2006. The Birds of North America Online doi:10.2173/bna.12), and based on feather emergence the bird was approximately 11–12 days old. The nestling had a total body length (tip of bill to tail bud) of 50.7 mm, and was 15.6 mm at its widest point. *Passer domesticus* is commonly found in urban settings, and often uses cavities in buildings for nesting. To the best of our knowledge this is the first documentation of *R. marina* eating an invasive bird in Australia.

We thank the Australian Museum for assistance with the bird identification.

CHRISTA BECKMANN (e-mail: c.beckmann@deakin.edu.au), and **LIGIA PIZZATTO** (e-mail: ligia.oceanica@gmail.com), School of Biological Sciences A08, University of Sydney, Sydney, NSW 2006, Australia.

FIG. 1. Female *Rhinella marina* with stomach contents of a nestling *Passer domesticus* and beetle.

TESTUDINES — TURTLES

***APALONE MUTICA* (Smooth Softshell). DIET.** Information on the diet of *Apalone mutica* in the Mississippi River is scanty. Routine fish surveys with trammel nets (Vogt 1983. Copeia 1980:368–371) in Cassville Slough, a side channel in Grant Co., Wisconsin, USA, resulted in the collection of 34 *A. mutica* during the period 2005–2011. We obtained gut contents from 17 adult females (carapace length: 239–301 mm, mean = 261 mm; mass: 0.97–2.22 kg, mean = 1.47 kg) that had died in the nets (living turtles were released), including at least one turtle from each year. Eight of the Cassville turtles were collected in late June, and the remaining nine in early August. Unpublished data were also available for a female (179 mm; 0.45 kg) collected in a fyke net in Devil's Run of the Fountain City Bay backwaters, Buffalo Co., Wisconsin (26 June 1975), and a male (182 mm; 0.40 kg) collected by seining in the Weaver Bottoms, Wabasha Co., Minnesota (24 August 1976) during a study of *A. spinifera* (Cochran and McConville 1983. J. Herptetol. 17:82–86).

Gut contents of *A. mutica* were dominated by aquatic insects. Sixteen of 17 turtles from Cassville Slough contained naiads of the large burrowing mayfly *Hexagenia*. Minimum counts in individual turtles, based on counts of head capsules or tusks, ranged from 10 to 151 (mean = 66.4). One of the Cassville turtles in August also contained remains of at least three adult *Hexagenia*. Two of the Cassville turtles each contained a caddisfly larval case, and one of these two also contained 17 pupae. One Cassville turtle contained a dragonfly naiad. The turtle from Devil's Run contained 7 *Hexagenia*, two dragonfly naiads, and 71 caddisfly larvae (many cases of sand grains or of leaf fragments had been swallowed whole), whereas the turtle from the Weaver Bottoms contained 23 caddisfly larvae, one dragonfly naiad, 15 chironomid larvae, and three unidentified insects.

One Cassville turtle contained a small crayfish (young-of-the-year), and ten contained the remains of small mollusks. One had eaten two helical snails (1–2 mm), six had eaten native mussels (< 1cm), and five had eaten Zebra Mussels (*Dreissena polymorpha*). Two turtles contained both native and zebra mussels. Most shells were unbroken, but shell fragments were present in five turtles.

Our results are consistent with some previous reports but provide new details. Although the importance of aquatic insects, including ephemeropterans, in the diet of *A. mutica* has been noted previously (e.g., Williams and Christiansen. 1981. J. Herptetol. 15:303–308), few studies have specifically mentioned *Hexagenia*. *Hexagenia* are abundant in many large aquatic habitats, including the upper Mississippi River (Fremling 1960. Iowa St. Univ. Agr. Home Econ. Exp. Sta. Res. Bull 482:842–852), where they are a major component of the diet of *A. spinifera* (Cochran and McConville, *op. cit.*). However, *Hexagenia* are also indicators of good water quality (Fremling 1964. Science 146:1164–1165); they declined in abundance historically in areas that were polluted or otherwise degraded and at least sometimes have reappeared when conditions ameliorated (Cochran and Kinziger 1997. Great Lakes Entomologist 30:89–92). Previous diet studies based on *A. mutica* collected in degraded habitats would not be expected to have found *Hexagenia* in great numbers.

Zebra Mussels have not been reported previously in the diet of *A. mutica*, but most studies pre-dated the colonization of the Mississippi River drainage by this exotic invasive species during the 1990s (McMahon and Bogan 2001. *In* J. H. Thorp and A. P. Covich [eds.], Ecology and Classification of North American Freshwater Invertebrates, 2nd ed., pp. 331–429. Academic Press, San Diego, California).

Unlike some previous surveys, we did not find terrestrial prey items in the diet of *A. mutica*. However, our samples were dominated by females caught in nets set in relatively deep, mid-channel habitat. Plummer and Farrar (1981. J. Herptetol. 15:175–179) noted that, unlike males, females foraged primarily in deep water and fed primarily on aquatic prey.

We thank the benefactors of the Saint Mary's University Science Internship Program. John Lyons of the Wisconsin Department of Natural Resources facilitated the collection of the softshells.

PHILIP A. COCHRAN (e-mail: pcochran@smumn.edu) and **NATHAN B. PETERSON** (e-mail: nbpete08@smumn.edu), Biology Department, Saint Mary's University of Minnesota, 700 Terrace Heights, Winona, Minnesota 55987, USA.

***GOPHERUS AGASSIZII* (Desert Tortoise). BURROW COLLAPSE.** In the deserts of the southwestern U.S., burrows are utilized by the Desert Tortoise to escape environmental extremes (reviewed by Ernst and Lovich 2009. Turtles of the United States and Canada. 2nd ed. Johns Hopkins Univ. Press, Baltimore, Maryland. 827 pp.). However, the potential for mortality through burrow collapse and entrapment is poorly documented. Nicholson and Humphreys (1981. Proceedings of the Desert Tortoise Council, pp. 163–194) suggested that collapse due to livestock trampling may cause mortality. In addition, Lovich et al. (2011. Chelon. Cons. Biol. 10[1]:124–129) documented a Desert Tortoise that used a steel culvert as a burrow surrogate. The culvert filled completely with sediment following a significant rain event, entombing the animal and ultimately resulting in its death. We note that this mortality was associated with an anthropogenic structure; because tortoises are prodigious diggers, one might hypothesize that they have the ability to dig out of collapsed natural burrows in most situations. Circumstances described here presented us with an opportunity to test this hypothesis.

On 5 January 2011, we observed four occurrences of adult telemetered Desert Tortoises (one male and three females) hibernating in separate burrows that collapsed at our study site on a utility-scale renewable energy wind farm (33.95168ºN, 116.667295ºW; WGS84) in southern Riverside Co., California, USA. In mid December 2010, winter rainstorms in southern California caused the partial collapse of several burrows distributed throughout the study site (Fig. 1). Wet soil above the mouth of the burrows slumped into the openings blocking the entrance. The lengths of the collapsed segments were not measured relative to total burrow length but each completely occluded the burrow opening. The collapsed burrows were not located near any anthropogenic structures.

One Desert Tortoise, a female (CL = 25 cm, mass = 2950 g), was found (5 January) covered with dirt outside of a collapsed burrow from which she presumably extricated herself. By 5 May 2011, this individual had been relocated five times, producing two clutches of eggs, suggesting normal behavior unaffected by the temporary entombment. The second female (CL = 25 cm, mass = 3100 g) also successfully dug out of her collapsed burrow at some point in early February, and by 6 May 2011, had been relocated three times exhibiting normal behavior. The third female tortoise (CL = 23.3 cm, mass = 2750 g) began excavating her burrow, as observed by one of the authors while peering into a small opening in the dirt, but did not complete the process until early April 2011. By 5 May 2011 she has been relocated three times. By mid-April the last tortoise (male, CL = 32.8, mass = 6275 g) was still inside his collapsed burrow, on the right side of center of the original opening (from observer's perspective), apparently unable to extricate himself. A different female tortoise (separate from those above) began excavating into the left side of this male's burrow (from the outside) but did not complete the process. During the course of the spring the soil surrounding the male dried to an adobe-like consistency. On 14 April 2011, one of the authors used a shovel to remove soil from the top and left side of the male. Even with the body partially exposed, the tortoise was so firmly embedded in the soil that he could not be lifted out without digging away more soil on the right side of the body. The tortoise was completely encased in hard loamy soil with no space for moving the head, limbs, or body, exactly as the tortoise reported by Lovich et al. (*op. cit.*). It is our opinion that this animal would have remained entombed and would have died if not excavated.

PHOTO BY J. ENNEN

FIG. 1. A burrow of *Gopherus agassizii*, approximately 30 cm wide, caved in following winter rains in December 2010. The burrow depicted was the domicile of the third female to excavate herself (April 2011).

Because of the conditions under which the natural burrows collapsed, the survival of the three female tortoises contrasts with the impending mortality of the male observed in this study. This is likely due to the fact that the females were not entombed in burrows oriented so as to allow the sun to bake the collapsed soil. When entombed under these conditions it appears that some tortoises may be unable to free themselves. Given the digging prowess of Desert Tortoises we hypothesize that this is not a frequent cause of mortality. However, temporary entrapment may result in physiological stress or late egress that translates into a delayed or complete loss of opportunity for early spring feeding and reproduction.

Support for our field studies is provided by the California Energy Commission (CEC). This study has been conducted under permits with the U.S. Fish and Wildlife Service and California Department of Fish and Game. This work was approved by Northern Arizona University's Institute for Animal Care and Use Committee (IACUC). E. Nowak and C. Drost provided useful comments on earlier versions of this manuscript.

***GRAPTEMYS FLAVIMACULATA* (Yellow-blotched Map Turtle). UNIQUE AERIAL BASKING BEHAVIORS.** The genus *Graptemys* (Emydidae) is the most diverse genus of North American turtles, with most species occurring within river systems that drain into the Gulf of Mexico (Lindeman, *in press*. The Map Turtle and Sawback Atlas: Ecology, Evolution, Distribution, and Conservation of the Genus *Graptemys*). One of these species, *G. flavimaculata*, is

a small species endemic to the Pascagoula River system of southeastern Mississippi, USA (Selman and Qualls 2009. Herpetol. Cons. Biol. 4:171–184). This species is most commonly observed basking aerially, with high basking densities associated with river bends and associated emergent deadwood snags that provide basking platforms (Lindeman 1999. Biol. Cons. 88:33–42). I report on two unique basking behaviors observed in *G. flavimaculata* (Leaf River, Forrest Co., Mississippi): 1) extensive shuttling on/off basking structures, and 2) head dipping into the water. To the best of my knowledge, neither of these behaviors have been reported in this species, with the first rarely reported in other species and the second reported for only one other turtle species, *Trachemys scripta scripta* (Auth 1975. Bull. Florida State Mus., Biol. Sci. 20:1–45.).

On 20 June 2007, a female *G. flavimaculata* was observed shuttling on and off the same log eight times (1343–1511 h) for a total basking time of 74 minutes out of 88 total minutes (Table 1); unfortunately no data loggers were deployed at this time to collect temperature data. On 10 September 2007, a juvenile female shuttled eight times on and off different branches and tangles (0857 and 1400 h), for a total basking time of 163 minutes out of 303 total minutes. Lastly, a male individual was noted on 8 April 2008 to shuttle 9 times between a log and floating log (0939 and 1305 h), for a total time of 147 minutes out of 206 total minutes. Observations 2 and 3 had temperature data associated with behaviors (Table 1).

Basking turtles were also observed on multiple occasions head dipping in the water before submerging. This behavior was observed twice on 17 July 2007 with two different individuals (one male, one female). Before they returned to the water, both individuals dipped only their heads under the water surface. The male did this twice at 1020 h and then returned to the water following 141 minutes of basking; the female did this once for approximately 15–20 sec before submerging after basking for 138 minutes. During the week prior to these observations, the Leaf River basin received several inches of rain causing water levels to be abnormally high and water temperatures to be unseasonably cool for July. Another observation of this behavior was made on 7 May 2008 when a male *G. flavimaculata* submerged the anterior portion of his body while his hindlimbs were clinging to the basking structure. During the 1–1.5 minutes exhibiting this behavior, he raised his head out of the water twice and then submerged. Environmental temperatures for all three observations are described in Table 1.

Extensive shuttling behavior exhibited by *G. flavimaculata* has not been previously reported. Presumably this behavior allows basking individuals to thermoregulate on a fine scale, as the temperature data indicate that optimal body temperatures appear to fall within a relatively narrow window between the water [WT] and ambient air [AT]/log temperatures [LT]. During the two observations with associated temperature data, WT and AT were initially similar, but log temperature was higher than WT. By the end of the observations, both AT and LT increased considerably and were warmer than WT. A study with a similar species, *Graptemys geographica* (Bulté and Blouin-Demers 2010. Oecologia 162:313–322), found that individuals operated within a fairly narrow range of body temperatures throughout the day and individuals could raise their body temperatures well above water temperatures, thus playing a critical role in thermoregulation. Further, the three observations occurred across most of the active season of this species (April, June, September) and with different sizes/sexes, thus indicating that this behavior is not limited to a particular season and/or sex.

To the best of my knowledge, head dipping behavior has only been described in one study with *T. s. scripta* (Auth 1975, *op. cit.*) with little discussion of the behavior. From these observations, head dipping appears to be either 1) a thermal "test" of the water temperature prior to submergence, or 2) a method to gain olfactory cues of the nearby environment (i.e., detect conspecifics, predators, prey items). However, it is unclear if "water testing" is a better explanation than olfaction due to the inability to determine underwater conditions (i.e., presence of a predator). "Water testing" could be plausible as cooler WT relative AT or LT was documented, but one might expect this to occur more often due

TABLE 1. Description of extensive shuttling and head dipping behaviors with *Graptemys flavimaculata* (Yellow-blotched Sawback). Water (WT), ambient air (AT), and sunlit log (LT) temperatures describe the environmental conditions.

Date, sex of individual (shuttling [S], head-dipping [HD])	Initial emergence time	Initial final WT (°C)	Initial final AT (°C)	Initial final LT (°C)	Basking duration for each time individual emerged (in minutes)									Final submergence time

to WT usually being cooler than AT/LT during the active months. Similarly, nesting female turtles have been observed "nuzzling" the ground (i.e., placing their head and chin on the soil surface) while on nesting forays, possibly to 1) gain olfactory cues to detect a better nest site, or 2) sense the texture, temperature, or moisture content of nesting substrate (Moore 2003. M.Sc. thesis, Southeastern Louisiana University, Hammond, Lousiana. 72 pp.; Morjan and Valenzuela 2001. J. Herpetol. 35:668–672). If head dipping and nuzzling are to test for water/soil temperatures, this could indicate that the head region of turtles might be acutely sensitive to temperatures and/or have a higher concentration of temperature receptors relative to the rest of the body; this would need to be verified in future studies. If head dipping was for olfaction, underwater cameras or a more controlled environment with addition of stimuli (i.e., conspecifics, predators) might elucidate the reason for this behavior.

I thank the U.S. Fish and Wildlife Service for providing funding for this and other projects. I also thank J. D. Odom for granting access permission to his private boat ramp on the Leaf River and P. Spencer for granting access to her privately-owned sandbars on the Leaf River.

***PODOCNEMIS EXPANSA* (Giant South American River Turtle). NESTING RANGE EXPANSION.** *Podocnemis expansa* is gregarious during nesting; even today, beaches are found in the Brazilian Amazon where hundreds of females might lay their eggs in a single night. The high consumption of this turtle's meat and eggs, as well as the ease with which it is captured, especially during nesting periods, has contributed to the decline in populations throughout its entire range and to extirpation in some places. Despite conservation and enforcement efforts, the species has been classified by the IUCN SSC FTTG as Critically Endangered (October 2010) (www.iucnredlist.org). Areas with high concentrations are well known, but regions at the limits of its range, where there are few individuals, are not yet completely known, partly due to difficult access and the extensive area where the species occurs.

In the Lower Xingu River there are known nesting sites for *P. expansa*, most notably on Embaubal beach (2.6784°S, 52.0186°W), in Senador José Porfírio (Pará state), but information is still lacking on the species' occurrence throughout this hydrographic basin. Here we report the first occurrence of *P. expansa* in the Upper Xingu River, although regional studies have indicated that this area is a potential habitat for the species (Pritchard and Trebbau 1984. The Turtles of Venezuela. Society for the Study of Amphibians and Reptiles, Caracas. 403 pp.). In 2010 we recorded and monitored the temperature of two *P. expansa* nests in the Xingu Indigenous Park (11.9346°S, 53.5298°W). These were the only nests found on the sandy beaches that are formed during the river's dry season throughout a monitored area of 13 km where *Podocnemis unifilis* frequently nests, and *Phrynops geoffroanus* do so less often. Nesting of *P. unifilis* in this area has been monitored since 2006, but it was only in 2010 that *P. expansa* nests were seen. *Podocnemis expansa* nesting occurred when the water level reached its lowest point, which is standard for this species.

We used data loggers (Ibuttons Maxim DSG1921G) to monitor the temperature throughout incubation, at 60-minute intervals. For the two nests, incubation lasted 65 and 78 days and the thermo-sensitive-period temperature (in the second third of the incubation period) was 29.4 ± 0.86°C (range = 28–31°C) and 28.7 ± 1.01°C (range = 26.5–32°C), respectively. These incubation temperatures and durations are compatible with the production of males (Lubiana and Ferreira Júnior 2009. Zoologia 26:527–533). Hatching success was 57% in one nest with 101 eggs and 52% in the other nest with 73 eggs. No predation attempts were recorded for the nests.

On 29 October 2010, a female was captured by one of the Indians while fishing with a hook and line near the same beach where the two nests were found. This female had a straight carapace length of 33.6 cm, straight carapace width of 25.5 cm, plastron length of 28.1 cm, plastron width of 19.8 cm and weight of 3.38 kg. Tissue was collected from this individual for comparative genetic analysis with individuals from other regions in the future. The Indians confirmed that they do occasionally capture *P. expansa* when fishing. During the same incubation period in 2010 our group also saw *P. expansa* tracks on at least two other beaches in the area.

Reports from indigenous people suggest that *P. expansa* was introduced in the 1960s, when the Xingu Indigenous Park was created, by its founders and some indigenous people. These animals came from populations on the Ilha do Bananal, in the Araguaia River, in São Felix do Araguaia (Mato Grosso state). The animals were released at about 20 km upstream from the site where we observed the nests. Their introduction had been to provide an additional food source, mainly because the Indians of that region very much appreciate the meat and eggs of *P. unifilis*. In the 1980s a new release of young *P. expansa* took place in rivers in the Upper Xingu. This time the individuals were from Rio das Mortes (Mato Grosso) (Vera Lúcia Ferreira Luz, Environmental Analyst, Head of RAN/ICMBio, pers. comm.). On both occasions the translocation of animals was carried out without considering the species' ecological needs and without approval from the relevant environmental entities. There are various signs that the information about the introduction of the species may be reliable: the apparent rarity of *P. expansa* in the region; the lack of knowledge among the indigenous peoples of the nests and nesting sites; few reports of adult individuals being captured; scant knowledge of the capture techniques used for the species; the fact that this species is not part of the traditional indigenous diet (while *P. unifilis*, common in the area, is an important food item); and the absence of this species in local myths and rites.

Knowledge of all nesting sites is important for the establishment of the species' range, especially in regions that have been only lightly affected by agricultural inroads and intensive fishing. The report of *P. expansa* in the Xingu Indigenous Park is important because of the large changes foreseen with the damming of the Xingu River to generate energy. Hydroelectric plants are planned upstream and downstream of this recorded site, and it is vital that the feeding and nesting areas of the species are known, to study the possible effects on their ecology caused by the change in the river's hydric regime. The genetic diversity of these individuals should be compared with that of turtles from other areas (principally in populations from the Lower Xingu and Araguaia River Basin). This will lead to a better understanding of the evolutionary dynamic of the species in the reported site and of its diversity distribution within this area at the limit of its range.

CROCODYLIA — CROCODILIANS

***ALLIGATOR MISSISSIPPIENSIS* (American Alligator). JUVENILE SITE FIDELITY.** *Alligator mississippiensis* is a highly adaptable, aquatic species, occupying a wide range of habitats in the southeastern United States (Elsey and Woodward 2010. *In* Manolis and Stevenson [eds.], Crocodiles. Status Survey and Conservation Action Plan. 3rd ed., pp. 1–4. Crocodile Specialist Group, Darwin). One prior telemetry study conducted on Rockefeller Wildlife Refuge in southwestern Louisiana found minimum home ranges of 12.0–616.5 ha (average 177.5 ha) for 15 immature female alligators, and minimum home ranges of 24.5–604.5 ha (average 228.6 ha) for 11 immature male alligators (McNease and Joanen 1974. Proc. SE Assoc. Game Fish Comm. Conf. 28:482–500). A recent large tag and recapture study found some juvenile alligators can disperse long distances (one moved >90 km), although many marked alligators stayed within the shallow marsh impoundments within which they were originally tagged (Lance et al. 2011. Southeast. Nat. [in press]).

Four recent major hurricanes impacted coastal marshes in Louisiana (Katrina and Rita in 2005, and Gustav and Ike in 2008, with massive storm surges in some cases pushing alligators previously tagged and marked for research studies northward (Elsey et al. 2008. Southeast. Nat. 7:737–743). Similar findings were noted after Hurricane Audrey with alligators being swept northward 4.8–16.1 km; it was also noted that alligator movement increases when marshes are flooded due to excessive rainfall or storm tides, with immature alligators responding more to flooding than adults (Chabreck 1965. Proc. SE Assoc. Game Fish Comm. 19:102–110). In one extreme case, a juvenile alligator from a local alligator farm was tagged and released to the wild in southwestern Louisiana six weeks before Hurricane Ike and was apparently swept away in the storm surge and recovered in extreme south Texas, some 489 km from its release site (Elsey and Aldrich 2009. Southeast. Nat. 8:746–749). In contrast, we herein report on four juvenile alligators from a group of eleven that were in a holding pen at Rockefeller Wildlife Refuge at the time of Hurricane Ike. All were presumably displaced by the storm surge (ca. 244 cm), yet have been recovered in close proximity to the original pen site, possibly demonstrating strong site fidelity.

As part of the alligator management program in Louisiana, a large scale tag and release program has been underway to monitor the survival of alligators released to the wild from farms. More recently we have considered the use of telemetry to evaluate survival and movement in the initial months after release to the wild. A pilot study was initiated in 2007 to evaluate transmitter attachment, retention, and detection capabilities under near field conditions (Wiebe 2008. Unpubl. report, Louisiana Department of Wildlife and Fisheries. 21 pp.). For these purposes, a 0.28 ha outdoor holding pen was constructed in early 2008 near the Rockefeller Wildlife Refuge headquarters in Grand Chenier, Louisiana to hold native wild and farm-raised juvenile alligators. The pen was initially stocked with 17 farm-raised alligators (obtained on 12 March 2008 from a commercial alligator farm) and 10 native wild alligators. The telemetry units were attached to the nuchal scutes (Wiebe, *op. cit.*) and the alligators were released to the outside pen over the next two days. The alligators appeared to easily adapt to the new environment, but by 29 March we observed one of the alligators basking on a feeding platform was missing the telemetry unit; the nuchal scutes were visibly torn. This was unexpected as similar attachment methods have been used successfully in other crocodilians (Brien et al. 2010. Herpetol. Rev. 41:305–308; Kay 2004. Herpetol. Rev. 35:354–357). However, those were larger animals with far more prominent nuchal scutes, and the relatively flat scutes in juvenile alligators likely being a contributing factor in unit loss. Despite the alligators readily accepting feed and exhibiting no evidence of intraspecific conflicts, loss of telemetry units continued to be a problem.

Over the next few months the pen was pumped dry and attempts were made to recover the animals and reattach telemetry units more securely (Wiebe 2008, *op. cit.*). On 20 May we replaced eleven of the alligators (previously farm-raised, mean total length 126 cm) back in the outside pen for further monitoring, each with one telemetry unit held in place by cables passing under the nuchal scutes and one attached to the tail.

Soon thereafter, Hurricane Ike impacted the region when it struck near Galveston Island, Texas on 13 September 2008, as previously detailed (Elsey and Aldrich, *op. cit.*). The storm surge at Rockefeller Refuge was estimated to be 244 cm and likely overtopped the fencing of the outside alligator enclosure, allowing alligators to escape or unwillingly be carried northward with the storm surge. We made a cursory inspection of the flooded pen area (accessible only by airboat) on 18 September, and could readily see loss of integrity to some areas of the fence, presumably allowing alligator escape. Refuge staff members were displaced from this site for several weeks due to localized flooding, lack of electricity, and general loss of infrastructure; thus we were unable to immediately monitor the fate of the eleven alligators that were in the pen at the time of Hurricane Ike's landfall.

On 15 October 2008, while doing landscape work in a pasture, an employee incidentally observed one of the alligators resting on a bank near a parked excavator. The alligator appeared well and was some 125 m from the enclosure (Fig. 1A). On a routine search for any remaining alligators that might still be within reception range, a second escaped/displaced alligator was recovered on 20 November 2008, using signals from the functioning telemetry unit(s) for guidance. This alligator was observed on floating vegetation, was then captured in good condition, and was determined to be ca. 135 m from the holding pen (Fig. 1B). With time, it became apparent many units were not functioning, possibly due to poor transmission in brackish water, loss of battery life, or damage due to saltwater corrosion after the

hurricane. Six months later, while catching wild alligators on 20 May 2009 for another research project, another of the 11 telemetered alligators was caught; it was recovered some 425 m (Fig. 1,C) from the outside holding pen site.

On 6 May 2011, an alligator was observed at ca. 1725 h basking near the refuge headquarters by one of us (RME) and the two missing tail notches were evident (suggesting it was an alligator released from a farm, Elsey et al. 2001. *In* Seebacher and Franklin [eds.], Crocodilian Biology and Evolution, pp. 426–441. Surrey Beatty and Sons, Chipping Norton, NSW). This prompted us to take some photographs for educational presentations and to possibly identify the year the alligator was released, due to the year-specific combination of tail notches used. One of us (WS) was able to identify the fifth and seventh tail scutes as having been removed (this "EG" tail notch identified it as a 2008 year release alligator). Upon closer observation, WS noted a telemetry unit was attached to the alligator's tail (Fig. 2). The site was some 475 m from the original holding pen (Fig. 1D), from where the alligator presumably escaped during Hurricane Ike, some 964 days earlier.

The following evening at ca. 1700 h, a similar-sized telemetered juvenile alligator with tail notches was again observed basking in nearly the same location. It was captured and appeared in excellent condition and both web tags in the feet were still present. The alligator was 167 cm in total length, compared to 127 cm when it was first measured on 12 March 2008. The alligator was released at the same site, and presumably the same alligator has been observed several times basking near the release site since (tail notches and telemetry unit on tail clearly seen).

Alligators have been shown to have a strong homing instinct (Chabreck, *op. cit.*; Rodda 1984. Behav. Ecol. Sociobiol. 14:241–246) as have other crocodilians (Read et al. 2007. PLoS ONE 9:1–5; Walsh and Whitehead 1993. Wildl. Res. 20:127–135; Webb et al. 1983. Aust. Wildl. Res. 10:403–406). It is unclear if the four juvenile alligators herein described were swept northward by the massive storm surge of Hurricane Ike and then returned, or if they were able to seek refuge in dens or burrows and avoid displacement. After the even more catastrophic Hurricane Rita in 2005, we documented (Elsey et al., *op. cit.*) a similar finding in 2007 of adult female alligators at nest sites within 20 m and 170 m of their prior nests sites (from seven years and three years earlier, respectively). Again it is unknown if this demonstrated a strong homing instinct if the alligators had been displaced, or if they remained on site despite the flooded conditions and high salinity environment post-hurricane.

The juvenile alligators in this study may have remained near the original pen site or returned to this area due to proximity to aquaculture fish ponds near the refuge headquarters, which provide permanent fresh water and seasonally available prey when ponds are stocked with fish fry or fingerlings. It is somewhat surprising however that the alligators remained in an area of relative high activity (despite being rural, all were located in very close proximity to the refuge headquarters, and were exposed to frequent vehicular traffic). Of note, staff had not (to our knowledge) observed marked alligators at the site where the most recently encountered alligator was seen, despite being immediately adjacent to a field work shop, perhaps suggesting the alligator recently returned to this site.

It also may be that alligators raised their entire life in a commercial farm setting are less likely to demonstrate a homing instinct, as reported in wild alligators after translocation (Chabreck, *op. cit.*). The alligators used in this study were obtained from a farm some 60 km west of the study pen site but to our knowledge made no attempts to return to that location. A short-term telemetry study likewise showed 75 of 78 farm-raised alligators and 43 of 44 native wild juvenile alligators dispersed less than 5 km from the release site or site of origin (Addison 1993. MS thesis, Louisiana State University, Baton Rouge, Louisiana. 79 pp.).

FIG. 1. Aerial map showing locations of four juvenile alligators relative to the original holding pen. Dates of recovery as noted in the text.

FIG. 2. The fourth alligator recovered, here seen basking on 6 May 2011. The telemetry unit is clearly visible on the tail.

It is of interest why some alligators seem to move extensively despite abundant, locally available quality habitat, while others remain within a relatively small area with little tendency to disperse. Individual behavior patterns of crocodilians may be an area for future studies.

We thank Dr. J. Nevarez for assistance with attachment of the telemetry units, and B. Baccigalopi, J. Bottolfs, D. Bourque, D. LeJeune, T. Marcantel, N. Miller, C. Montiero, R. Perry, and K. Trahan for assistance throughout the pilot telemetry study.

SQUAMATA — LIZARDS

***AMEIVA AMEIVA* (Giant Ameiva). PREDATION.** *Ameiva ameiva*, a diurnal teiid lizard widely distributed across Central and South America, ranges from Panamá to Argentina (Vanzolini et al. 1980. Répteis das Caatingas, Acad. Bras. de Cienc., Rio de Janeiro; Vitt and Colli 1994. Can. J. Zool. 72:1986–2008; Sartorius et al. 1999. Biol. Cons. 90:91–101). Hawks, owls and snakes are well-known predators of *A. ameiva* (Santos and Germano 1996. Herpetol. Rev. 27:143; Tozetti et al. 2005. Herpetol. Rev. 36:443–444; Granzinolli et al. 2007. Herpetol. Rev. 38:449), but few published reports of predation by mammals exist. Rocha and Vrcibradic (1998. Cienc. e Cult. 50:364–368) reported predation by the Four-eyed Opossum (*Philander frenata*); no reports involve armadillos. Hence, we add to the predator set reported for *A. ameiva* with an observation of predation by the Nine-banded Armadillo (*Dasypus novemcinctus*).

At 2205 h on 23 October 2008, we observed a *D. novemcinctus* prey on an *A. ameiva* while traveling a dirt road near the city of Miranda, Mato Grosso do Sul, central-west Brazil (20.07833°S, 56.32444°W, datum: WGS84; elev. 177 m). The event occurred in vegetation best described as upland Pantanal savanna. As soon as we stopped the car, a *D. novemcinctus* that had just been observed crossing the road began to forage in leaf litter beneath shrubs about 5 m off the road. Within seconds, it attacked an adult male *A. ameiva* (101 mm SVL, 268 mm tail). The attack lasted less than a minute, with the armadillo killing its prey with its mouth and foreclaws. When we approached, the *D. novemcinctus* abandoned its prey and fled. Bite wounds had been inflicted to the left shoulder and the right thigh of the *A. ameiva*.

Armadillos are opportunistic, preying principally on invertebrates, but occasionally consume small vertebrates like amphibians and reptiles and other items such as plant material (Galbreath 1982. *In* J. A. Chapman and G. A. Feldhamer [eds.], Wild Mammals of North America, pp. 71–79. Johns Hopkins Univ. Press, Baltimore, Maryland). This is the first documented predation of *A. ameiva* by an armadillo.

FIG. 1. *Ameiva ameiva* being predated by nocturnally foraging Nine-banded Armadillo (*Dasypus novemcinctus*).

The *Ameiva ameiva* specimen was deposited at the Coleção Herpetológica do Museu de Zoologia da Universidade Federal da Bahia (MZUFBA–LAG1329). Jeff King and Ryan Watson provided helpful suggestions.

***ANOLIS* SPECIES. FRUGIVORY.** Frugivory has been reported for more than 200 species of lizards (Valido and Olesen 2007. In A. J. Dennis, E. W. Schupp, R. A. Green, and D. A. Westcott [eds.], Seed Dispersal: Theory and its Application in a Changing World. CAB International), including 17 species of the genus Anolis (Herrel et al. 2004. Oecologia 140:160–168). In Puerto Rico, the consumption of fruits has been reported for two intermediate sized Anolis species, A. evermanni (Lister 1981. Ecology 62:1548–1560; Reagan 1996. In Reagan and Waide [eds.], The Food Web of a Tropical Rain Forest, pp. 321–345. Univ. of Chicago Press, Illinois) and A. monensis (Schwartz and Henderson 1991. Amphibians and Reptiles of the West Indies. University of Florida Press, Gainesville, Florida), and for the giant species A. cuvieri (Losos 1990. Carib. J. Sci. 26:65–66; Perez-Rivera 1985. Carib. J. Sci. 21:101–103). Aside from reports of seeds from stomach content analyses or fecal pellets of these three species, little is known about frugivory in Anolis from Puerto Rico. Here, we report incidental observations of frugivory for another three Anolis species of small to intermediate size.

On 5 May 1998, between 0900 and 0930 h, we observed an individual of *A. stratulus* picking and carrying away a single sweet and sticky fruit of the Wild Balsam Apple (*Momordica charantia*) in a shaded coffee plantation at the north-central part of the island. The fruits of the Wild Balsam Apple are dark yellow to orange when ripe and split open to reveal several seeds 12–16 mm long, covered with a red flesh (Acevedo-Rodríguez and Woodbury 1985. The Vines of Puerto Rico Vol. 1: 202). *Anolis stratulus* also has been reported consuming intra- and extra-floral nectar (Perry and Lazell 1997. Herpetol. Rev. 28:150–151; Ríos-López 2004. Herpetol. Rev. 35:386).

During the morning of 16 April 1999, we observed an individual *Anolis gundlachi* eating fruits of Red Palicourea (*Palicourea crocea*) at the Río Abajo State Forest in the northern kasrt region of Puerto Rico. These fruits are ovoid to globose, 4–6 mm in diameter and dark red, purple, or black (Liogier 1997. *In* Descriptive Flora of Puerto Rico and Adjacent Islands. Vol. 5. Editorial de la Universidad de Puerto Rico, San Juan, PR. 436 pp.). This same day we observed a male *A. krugi* consuming the white fruits of a stinging nettle (*Urera baccifera*). These fruits are white or pinkish, spongy, and watery (Little et al. 1974. *In* Trees of Puerto Rico and the Virgin Islands. Vol. 2. Agriculture Handbook 449. U.S. Department of Agriculture, Washington, DC. 1024 pp.). Both lizards picked the fruits and ingested them while perching in the respective plants. The report for *A. krugi* represents the first for a grass-bush anole eating fruits (Losos 2009. Lizards in an Evolutionary Tree: Ecology and Adaptive Radiation of Anoles. University of California Press, Berkeley. 507 pp.).

Body sizes, as well as ecological factors such as food limitation, low predation pressures, and high lizard densities, have been proposed to explain frugivory by lizards within insular ecosystems (see Valido and Olese, *op. cit.*; Herrel et al., *op. cit.*; Olesen and Valido 2003. Trends Rev. Ecol. Evol. 18:177–181). Our observations suggest that frugivory in small-sized lizards (size range 40–63 mm) might be of ecological importance in nature. Detailed studies are needed in order to better understand the factors that determine frugivory in *Anolis* lizards, as well as their potential role as seed dispersers. Given that *Anolis* lizards occur at high densities in Caribbean Islands, omnivory and seed dispersal by these lizards must be important in energy and mass flow as well as in the succession and regeneration of tropical forests.

SONDRA I. VEGA-CASTILLO and **ALBERTO R. PUENTE-ROLÓN**, Department of Biology, University of Puerto Rico at Río Piedras, P.O. Box 23360, San Juan, Puerto Rico 00931-3360; e-mail: sondravega@yahoo.com.

***ATLANTOLACERTA ANDREANSKYI* (Atlas Dwarf Lizard). ABNORMAL SCALATION.** In snakes and lizards, femoral glands produce secretions used for intraspecific communication. These secretions may reveal chemical information including self-recognition, conspecific discrimination, marking of territories, male dominance status, and reproductive condition (Houck 2009. Annu. Rev. Physiol. 71:161–76; Martin et al. 2007. Ecology 21:568–576). Although there have been several reports of supernumerary femoral pores in lacertid lizards (Kaliontzopoulou and Carretero 2006. Herpetol. Rev. 37:470–471), this is the first observation of total absence of femoral pores.

During an extensive survey, we studied the morphology of 142 individuals (males and females) from seven localities across the distribution of *Atlantolacerta andreanskyi*, a high-altitude endemic lacertid from the Atlas Mountains, Morocco. In this species adult males typically exhibit enlarged femoral pores when compared with other lacertids (e.g., *Podarcis*) and the two rows of femoral pores come into contact at the base of the ventral scales, while in females, as in most lacertids, they are significantly smaller (Arnold and Ovenden 2002. A Field Guide to the Reptiles and Amphibians of Britain and Europe. Ed. Collin, 288 pp.) and the two rows are not in contact (Fig. 1). Interestingly, of 70 female individuals studied, 16% had incomplete rows and 56% did not possess any femoral pores (Fig. 2), while all males surveyed exhibited a normal development of the femoral pores. This observation was common and present in all the populations. Busack (1987. Amphibia-Reptilia 8:231–236) estimated mean adult body size of this species at 41.9 mm SVL with females with oviductal eggs ranging 44–53 mm SVL (N = 8), indicating that all individuals analyzed in our study were adults. Interestingly, the median size of the females analyzed with no femoral pores (47.8 mm) was slightly larger than the females with femoral pores (44.8 mm) (Busack, *op. cit.*).

Kaliontzopoulou and Carretero (*op. cit.*) reported accessory femoral pores in one specimen of the lacertid, *Podarcis bocagei*. The authors suggested environmental stress as a cause of this abnormality because the animal was found in a cornfield where pesticides were commonly used. Because *A. andreanskyi* occurs only at altitudes above 2000 m, in widely isolated populations with limited distributions, environmental stress seems unlikely to be the cause. Instead, factors such as isolation and inbreeding might be involved, as suggested by Walker (1980. J. Herpetol 14:417–418). In Walker's (*op. cit.*) observations, the abnormalities were found in both sexes, while we found it present only in females. This fact might be due to selective pressures acting on

FIG. 1. Female specimens of *Atlantolacerta andreanskyi* from Oukaimeden, Morocco (left and right). White arrows show the femoral pores.

FIG. 2. Female specimens of *Atlantolacerta andreanskyi* from Tamelt-elt (on the left) and Tizin-Tichka (on the right), High Atlas, Morocco. The black arrows show the place were the row of femoral pores should be.

males and related to sexual selection. Femoral pore secretions produced are directly related to the levels of circulating androgens (Houck, *op. cit.*) and they have been proposed to be the basis of female mate choice, being important in individual male recognition and dominance status, and related to a higher reproductive success (Houck, *op. cit.*).

Fieldwork was funded by FCT grant PTDC/BIA-BDE/74349/2006 to MB. All research was accomplished in accordance with all applicable institutional animal care guidelines and with all required state permits. We thank Antigoni Kaliontzopoulou and Miguel Carretero for their help discussing the pictures and to all colleagues from CIBIO who assisted during fieldwork.

MAFALDA BARATA, Centro de Investigação em Biodiversidade e Recursos Genéticos, Campus Agrário de Vairão, 4485-661 Vairão, Portugal / Departamento de Biologia, Faculdade de Ciências da Universidade do Porto, 4099-002 Porto, Portugal / Institute of Evolutionary Biology, Passeig Marítim de la Barceloneta, 37-49, E-08003 Barcelona, Spain (e-mail: mrbarata@gmail.com); **D. JAMES HARRIS**, Centro de Investigação em Biodiversidade e Recursos Genéticos, Campus Agrário de Vairão, 4485-661 Vairão, Portugal / Departamento de Biologia, Faculdade de Ciências da Universidade do Porto, 4099-002 Porto, Portugal (e-mail: james@mail.icav.up.pt); **ANA PERERA**, Centro de Investigação em Biodiversidade e Recursos Genéticos, Campus Agrário de Vairão, 4485-661 Vairão, Portugal (e-mail: perera@mail.icav.up.pt).

***CERCOSAURA ARGULUS* (Elegant Eyed Lizard). ARBOREAL BEHAVIOR.** *Cercosaura argulus* is a relatively uncommon inhabitant of the Amazonian forest (Avila-Pires 1995. Zoologische Verhandelingen Leiden 299:1–706). It is most commonly encountered in leaf litter (Vitt et al. 2003. Can. J. Zool. 81:302–312), but was documented up to 1.5 m on low vegetation by Vitt et al. (*op. cit.*) and up to 2.0 m by Duellman (2005. Cusco Amazonico. Comstock Publishing Associates, Ithaca, New York. 433 pp.).

On 20 March 2011, an adult specimen of *Cercosaura argulus* was captured at approximately 2145 h on the ground during a routine quadrat search at Sachavacayoc Centre, Tambopata

Province, Madre de Dios, Peru (12.86250°S, 69.36566°W; 94% relative humidity; 23.4°C ambient temperature). The animal was likely disturbed while sleeping and was caught while crawling through leaf litter. At approximately 2210 h the lizard was released near the base of a tree that measured ca. 43 cm DBH. The lizard walked briefly around the base and then started to climb directly up the trunk of the tree. Unlike most rainforest trees, this tree did not have buttresses, but had a straight trunk that was covered by foliose lichens, presumably making the surface texture easier to climb. We watched and video recorded the lizard for approximately 30 min., during which time the lizard slowly, steadily climbed straight up the trunk to over 10 m in height, stopping occasionally and then continuing to proceed. After the 10 m mark we lost sight of the lizard as it continued its upward climb. No previous records exist of a *C. argulus* climbing to such a height.

***CROTAPHYTUS COLLARIS* (Eastern Collared Lizard). COMMUNAL BRUMATION.** *Crotaphytus collaris* can be found in appropriate habitat throughout central and western United States and northcentral Mexico. Southwestern Colorado and southeastern Utah represent the northwestern limits of the range of *C. collaris*. At 1545 h on 16 April 2011 with an air temperature of 16°C, three adult male *C. collaris* were observed in aggregation emerging from brumation from a hibernaculum opening on a south-facing rocky slope in extreme western La Plata Co., Colorado, USA, ca. 5.8 km W of Red Mesa, Colorado (1995 m elev.) (Fig. 1). The habitat at this site is pinyon-juniper woodland with expanses of agricultural land. Because weather prior to this observation had been unseasonably cold, it is very likely that 16 April was the first date of emergence for these lizards. The lizards spent considerable time basking at the burrow site, occasionally moving back and forth from the entrance. Occasional territorial posturing was observed, but for the most part they appeared uninterested in intraspecific interactions. The lizards were observed during a 1 h period.

The same site was revisited at 1150 h the next day (17 April) with an air temperature of 20°C. Three adult male *C. collaris* were seen again at the entrance and in close proximity to the same hibernaculum opening. It is presumed that, based on color pattern differences, these three males were the same as those observed the day prior. Again there was little activity over a 2 h observation period, although occasionally a single lizard would enter the burrow opening and re-emerge after several minutes. To our knowledge, observations of communal brumation for this lizard are unreported.

FIG. 1. Three adult male *Crotaphytus collaris* at the entrance of a communal hibernaclum during spring emergence at a rocky outcrop in western La Plata Co., Colorado, USA.

BARNEY OLDFIELD, 443 CR 110, Hesperus, Colorado 81326, USA (e-mail: oldcrota@me.com); **DANIEL KEYLER**, Department of Experimental & Clinical Pharmacology, University of Minnesota, Minneapolis, Minnesota 55455, USA (e-mail: keyle001@umn.edu).

***CTENOSAURA OEDIRHINA* (Roatan's Spiny-tailed Iguana). LIMB REGENERATION.** Limb regeneration has been observed in *Lacerta, Liolaemus,* and *Sceloporus* (Bellairs and Bryant 1985. *In* C. Gans and F. Billett [eds.], Biology of the Reptilia, Volume 15, Development B, pp. 387–392. John Wiley & Sons, New York). Here I report on the first case of this observation within Iguaninae.

On 20 October 2010, an individual *Ctenosaura oedirhina* was captured at Gumbalimba Park and Reserve on the western end of Roatan Island, Islas de la Bahia, Honduras (16.282883°N, 86.595083°W). The right hind limb of the individual appeared to be regenerated and looked much like that of a regenerated tail (Fig. 1). This individual was of normal size and did not seem to be disadvantaged by this deformity. Photos have been deposited under USNM Herp Image 2731, 2732.

STESHA A. PASACHNIK, Bay Islands Foundation, Roatan, Honduras; Department of Ecology and Evolutionary Biology, University of Tennessee, Knoxville, Tennessee 37996, USA; e-mail: spasachn@utk.edu.

PHOTO BY S. A. PASACHNIK

FIG. 1. *Ctenosaura oedirhina* with a regenerated hind limb, observed at Gumbalimba Park and Reserve, Roatan, Honduras.

***CTENOSAURA OEDIRHINA* (Roatan Spinytail Iguana). ENDOPARASITES.** *Ctenosaura oedirhina* is known only from Isla de Roatán, Isla de Santa Elena, Isla Barbaretta, and various small islets around Roatán, Honduras (Pasachnik et al. 2010. *In*: IUCN Red List of Threatened Species. Version 2010.4. www.iucnredlist.org; accessed 18 April 2011). There are, to our knowledge, no reports of endoparasites from this species. The purpose of this note is to establish the initial helminth list for *C. oedirhina*.

One adult male (roadkill) *C. oedirhina* was collected on 25 March 2011, near Oakridge on Isla de Roatán, (16.408617°N, 86.364883°W, datum WGS84; elev. 73 m), Departamento de Islas de la Bahía, Honduras. The individual weighed 540 g, had a SVL of 240 mm and a tail-length of 346 mm, although visibly stubby. The intestines were found to contain numerous nematodes,

which were preserved in 95% ethanol. A subsample was cleared in glycerol, mounted on a glass slide, coverslipped, examined under a compound microscope and identified as *Ozolaimus ctenosauri*. Voucher nematodes were deposited in the United States National Parasite Collection, Beltsville, Maryland, USA as USNPC (104699).

Ozolaimus ctenosauri was originally described from the caecum of *Ctenosaura acanthura* from Oaxaca, Mexico by Caballero (1938. Ann. Trop. Med. Parasitol. 32:225–229). It has been reported from other Mexican reptiles: *Ctenosaura pectinata* by Prado-Vera (1971. Estudio taxonómico de algunos nemátodos parásitos de reptiles de México. Tesis, Univ. Nac. Auton. México, 101 pp.), Moravec et al. (1996. J. Parasitol. 82:1011–1016), and Mayen-Pena and Salgado-Maldonado (1998. J. Helminthol. Soc. Washington 65:108–110); an unidentified iguana by Caballero and Cerecero (1943. An. Inst. Biol. Univ. Nac. Auton. México 14:527–539); and a rattlesnake, *Crotalus polystictus*, by Caballero (1939. An. Inst. Biol. Univ. Nac. Auton. México 10:73–82). It has also been reported in *Ctenosaura similis* from Costa Rica by Bravo-Hollis and Brenes (1960. An. Institut. Biol. Univ. Nac. Auton. México 30:209). *Ctenosaura oedirhina* represents a new host record for *Ozolaimus ctenosauri*; Isla de Roatán, Honduras is a new locality record.

Parasites were collected under permit DICTAMEN DVS-ICF-054-20120, granted by the Instituto Nacional de Conservacion y Desarrollo Forestral, Areas Protegidas y Vida Silvestre.

STEPHEN R. GOLDBERG, Department of Biology, Whittier College, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu); **CHARLES R. BURSEY,** Pennsylvania State University, Shenango Campus, Biology Department, Sharon, Pennsylvania 16146, USA (e-mail: cxb13@psu.edu); and **STESHA ANN PASACHNIK,** Bay Islands Foundation: Roatan Branch, Islas de la Bahia, Honduras (e-mail: sapasachnik@gmail.com).

***CTENOSAURA SIMILIS* (Black Spiny-tailed Iguana). DIET.** Iguanas in the genus *Ctenosaura* have been documented to eat a wide variety of items, including, but not limited to: arthropods (some potentially noxious), birds, bats, rodents, their own skin, juvenile lizards, fecal material, ctenosaur eggs, parts of conspecifics, and a variety of plants including at least one noxious species, *Croton suberosus* (Alvarez del Toro 1960. Los Reptiles de Chiapas. Inst. Zool. Estado Tuxtla Gutierrez, Chiapas; Blázquez and Rodriguez-Estrella 2007. Biotropica 39:496–501; Campbell 1998. Amphibians and Reptiles of Northern Guatemala, the Yucatán, and Belize. Univ. Oklahoma Press, Norman, Oklahoma; Coti and Ariano 2008. Iguana 15:142–149; Durtsche 2004. Physiol. Biochem. Zool. 77:459–470; Fitch et al. 1971. Southwest. Nat. 15:397; Fitch and Henderson 1978. Univ. Kansas Sci. Bull. 51:483–500; Henderson 1973. J. Herpetol. 7:27; Mora 1991. Bull. Chicago Herpetol. Soc. 26:197–198; Van Devender 1982. *In* Burghardt and Rand [eds.], Iguanas of the World: Their Behavior, Ecology, and Conservation, pp. 163–183. Noyes Publications, Park Ridge, New Jersey). We report on *Ctenosaura similis* consuming a post-mortem *Rhinella marina*.

Herbivory is the most common dietary strategy within the iguanine lizard clade (Iverson 1982. *In* Burghardt and Rand [eds.], *op. cit.*, pp. 60–76; Sites et al. 1996. Mol. Biol. Evol. 13:1087–1105; Torres-Carvajal 2007. J. Herpetol. 41:528–531). Non-herbivorous diets are rarely described within this clade, although limited carnivory in *Cyclura* (Auffenburg 1982. *In* Burghardt and Rand [eds.], *op. cit.*, pp. 84–116; Hayes et al. 2004. *In* Alberts et al. [eds], Iguanas, Biology and Conservation, pp. 232–257. Univ. California Press, Berkeley, California; Iverson 1979. Bull. Florida St. Mus. 24:175–358), *Ctenosaura* (Blázquez and Rodriguez-Estrella, *op. cit.*; Grant 1967. Copeia 1967:223–224; SAP, pers. obs.), *Dipsosaurus* (Norris 1953. Ecology 34:265–287), and *Iguana* (Loftin and Tyson 1965. Copeia 1965:515), and limited insectivory in *Ctenosaura* (Blázquez and Rodriguez-Estrella, *op. cit.*; Montanucci 1968. Herpetologica 24:305–315), *Cyclura* (Goodman 2007. Carib. J. Sci. 43:73–86), *Dipsosaurus* (Minnich and Shoemaker 1970. Am. Midl. Nat. 84:496–509; Norris, *op. cit.*) and *Iguana* (Campbell, *op. cit.*; Hirth 1963. Ecology 44:613–615) have been described. A less common dietary behavior in iguanine lizards is scavenging of vertebrate carcasses, with observations only from *Ctenosaura pectinata* (Grant, *op. cit.*) and *Iguana iguana* (Loftin and Tyson, *op. cit.*). In addition, *Ctenosaura similis*, *C. pectinata,* and *C. palearis* exhibit generalized insectivory as juveniles, making the ctenosaurs the only iguanine genus to demonstrate a predominant diet other than herbivory in any life stage (Coti and Ariano, *op. cit.*; Durtsche 2000. Oecologia 124:185–195, and 2004, *op. cit.*; Fitch and Hackforth-Jones 1983. *In* Janzen [ed.], Costa Rican Natural History, pp. 394–396. Univ. Chicago Press, Chicago, Illinois; Montanucci, *op. cit.*; Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna Between Two Continents, Between Two Seas. Univ. Chicago Press, Chicago, Illinois).

Ctenosaura similis exhibits a further deviation from a fully herbivorous diet with an ontogenetic shift toward omnivory in adults (Savage, *op. cit.*; Torres-Carvajal, *op. cit.*), foraging on such things as vegetation, arthropods, birds, bats, ctenosaur eggs, conspecifics and other lizards (Campbell, *op. cit.*; Fitch et al., *op. cit.*; Fitch and Hackforth-Jones, *op. cit.*; Fitch and Henderson, *op. cit.*; Henderson *op. cit.*; Hotton 1955. Amer. Midl. Nat. 53:88–114; Mora, *op. cit.*; Traveset 1990. Amer. Midl. Nat. 123:402–404; Van Devender, *op. cit.*). Torres-Carvajal (*op. cit.*) has provided dental evidence correlated with a shift towards carnivory in adult *C. similis*, though it is not clear how large of a role carnivory plays, as field documentation of this sort is lacking.

One adult *C. similis* was observed feeding on and dragging away a dead adult Marine Toad (*Rhinella marina*) on 19 June 2008 in Esparza, Puntarenas, Costa Rica (9.989195°N, 84.711373°W). The iguana was first observed feeding on the toad at the edge of the road at approx. 1100 h. The iguana was thrashing its head violently, presumably to break the toad into pieces for consumption. When disturbed the iguana dropped the toad and fled from the road, but returned shortly and dragged the toad off of the

FIG. 1. Adult *Ctenosaura similis* consuming a post mortem Marine Toad, *Rhinella marina*.

road, and continued to dismember it. The iguana was clearly an adult based upon its size (Fig. 1). The entire observation lasted for approx. 20 min., and additional digital footage is available from the authors.

Though this is a single observation, it supports an ontogenetic shift to an omnivorous diet in *C. similis*, thus suggesting that carnivory in ctenosaurs may be more prevalent than previously thought. In addition this demonstrates that *C. similis* is one of few opportunistic scavengers of vertebrate carcasses in the iguanine lizard clade.

We thank numerous local volunteers who aided us in identifying areas where iguanas could be found, and John Iverson and Arthur Echternacht for their insight. Funding for this project was provided by the University of Tennessee, Knoxville. A permit for research in Costa Rica was obtained with the help of Francisco Campos Rivera and Organización para Estudios Tropicales and was provided by Ministerio del Ambiente y Energia Sistema Nacional de Áreas de Conservación. A photograph was deposited at the Milwaukee Public Museum as MPM Herp Photo P758. A digital recording of this observation is available from the authors.

STESHA A. PASACHNIK, Department of Ecology and Evolutionary Biology, University of Tennessee, Knoxville, Tennessee 37996, USA (e-mail: spasachn@utk.edu); **JEFFREY P. CORNEIL,** Redmond, Washington 98052, USA (e-mail: jeffpc@myuw.net)

***ENYALIUS PERDITUS*. DEATH-FEIGNING.** *Enyalius perditus* is an Atlantic forest species of Brazil. It inhabits humid areas with lush vegetation and closed canopies (Jackson 1978. Arq. Zool. 30:1–79). This species is a semiarboreal forest-dweller that feeds exclusively on small invertebrates, and appears to be sensitive to forest structure and also sensitive to fragmentation, logging, and forest degradation (Dixo and Metzger 2009. Oryx 43:435–442). However, little is known about the natural history and ecology of *E. perditus*.

Death-feigning, also called tonic immobility or thanatosis, is an innate anti-predator behavior. In squamates, death-feigning is a widespread defensive tactic that is described from several different families, such as Anelytropsidae (Torres-Cervantes et al. 2004. Herpetol. Rev. 35:384), Leptotyphlopidae, Colubridae, Elapidae (Gehlbach 1970. Herpetologica 26:24–34), Crotaphytidae (Gluesing 1983. Copeia 1983:835–837), Scincidae (Langkilde et al. 2003. Herpetol. J. 13:141–148) and Tropiduridae (Bertoluci et al. 2006. Herpetol. Rev. 37:472–473; Machado et al. 2007. S. Am. J. Herpetol. 2:136–140). Herein we present data on death-feigning in *E. perditus* with a brief description of this behavior. The primary role of death feigning appears to be enhancing crypsis by ceasing movement.

FIG. 1. Death-feigning posture in a female *Enyalius perditus*.

We collected two *E. perditus* specimens during the inspection of drift fences with pitfall and funnel traps. On 12 October 2008, in the Reserva Biológica Municipal Santa Cândida (21.754917°S, 43.396833°W, WGS 84, 783 m elev.), in the municipality of Juiz de Fora, Minas Gerais State, Brazil, we collected a female (SVL 76.7 mm) and on 6 October 2008, in the Reserva Biológica Municipal Poço D'Anta (21.754278°S, 43.310889°W, WGS 84, 848 m elev.), we collected a male of *E. perditus* (SVL 71.4 mm) in the same municipality. Both lizards exhibited death-feigning behavior when they were removed from the traps and when manipulated in the laboratory to perform marking procedures and/or morphometric analysis. The lizards became immobile, lying belly-up, crossing the limbs over the stomach and closing the eyelids, although in some cases the eyes remained opened. Lizards remained motionless during manipulation with the legs and arms usually capable of being moved by the observer to any position with the lizard maintaining that position. The death-feigning posture persisted even after the animal was gently placed upside down. Lizards recovered after 15–30 min., subsequently fleeing.

Although we collected a total of 22 lizards, death-feigning behavior was observed only in these two specimens. However, we have previously observed death-feigning in many other individuals of *E. perditus* during the course of species inventories for study areas. Most specimens exhibited thanatosis when captured (Fig. 1). In all cases, the animals displayed a similar pattern of behavior and posture. We believe these observations to be the first records of death-feigning in *E. perditus*.

We thank C. H. V. Rios and W. L. Ouverney Jr. for field assistance and T. M. Machado for valuable suggestions on the manuscript. We acknowledge a grant from the Cordenação de Aperfeiçoamento de Pessoal de Nível Superior (CAPES) for the financial support and also IBAMA for the authorization for animal capture issued under the number 17074-1.

***GALLOTIA CAESARIS* (Caesar's Lizard). NECTARIVORY.** Plant-lizard mutualistic interactions (pollination and seed dispersal) have been considered a phenomenon more frequently detected on islands due to the high densities commonly seen in insular lizards (Olesen and Valido 2003. Trends Ecol. Evol. 18:177–181). Lizards experience stronger intraspecific competition, favored by a lower predation risk and arthropod food supply compared to mainland taxa, expanding their diet to incorporate novel food resources (e.g., fruit pulp and floral rewards; Olesen and Valido, *op. cit.*). This appears to be the case observed in endemic Canarian lizards, *Gallotia* spp., which include a signicant amount of plant matter in their diets, whereas their closest continental relatives are mainly insectivorous (Carretero et al. 2006. Rev. Esp. Herpetol. 20:105–117; Martín et al. 2005. Zoology 108:121–130; Valido and Nogales 2003. Amphibia-Reptilia 24:331–344; Van Damme 1999. J. Herpetol. 33:663–674). The role of *Gallotia* spp. as seed dispersers of Canarian flora has been well established, with fleshy fruit as the most significant component of their

FIG. 1. *Gallotia caesaris* visiting *Echium hierrense* (Boraginaceae) inflorescences from El Hierro, Canary Islands. The tail seems to play an important role as a prehensile appendix as the lizard climbs to higher flowers.

diet year round (e.g., *G. galloti*; Valido and Nogales 1994. Oikos 70:403–411). However, their role as pollinators has received less attention despite nectar-feeding field observations on native and exotic flora (Font and Ferrer 1995. Herpetol. Rev. 26:35–36; Valido et al. 2002. Acta Oecol. 23:413–419; Valido et al. 2004. J. Biogeogr. 31:1945–1953). Most of these observations refer to the Canary Lizard (*G. galloti*) from Tenerife, with the unique exception of *G. caesaris* from El Hierro observed visiting *Euphorbia lamarckii* flowers (Speer 1994. Salamandra 30:48–54). Here, we report a new account of nectarivory and presumptive pollinating behavior by *G. c. caesaris* on flowers of *Echium hierrense* (Boraginaceae); both are endemic taxa from El Hierro (27.733333°N, 18.05°W), the smallest and the westernmost island of the Canarian archipelago. Observations were made in the south of the island, at a xeric scrubland area known as El Lajial (255 m elev.).

From 20 to 22 April 2007, we performed daily 2-h monitoring (approximately 1000–1200 h), during which we observed *G. caesaris* visiting flowers of *E. hierrense*. In each of these periods, one male individual climbed the same plant three to four times, visiting different flowers from the same inflorescence (Fig. 1). Occasionally, we also saw the aforementioned lizard accompanied by a conspecific crawling up other inflorescences of the same plant. In both cases, lizards visited flowers legitimately (i.e., the snout brushed against the anthers and stigma of the flowers as they clearly licked nectar from them). We never detected agonistic interactions between lizards, nor did we observe lizards trying to capture pollinating insects (mainly Hymenoptera) while in the inflorescences.

Lizards are not the only flower visitor of *E. hierrense*. In the Canary Islands, *Echium* species are considered to be mainly bee-pollinated (Dupont and Skov 2004. Int. J. Plant Sci. 165:377–386). However, the endemic *E. wildpretii*, distributed in the arid high-altitude sub-alpine vegetation zone, is also visited by *Gallotia* lizards (Valido et al. 2002, *op. cit.*). Our observations suggest the possibility of more *Gallotia-Echium* interactions in the Canarian archipelago. This raises the question of what intrinsic (e.g., floral rewards) and extrinsic (e.g., water scarcity) plant factors promote interactions and how these interactions impact *Echium* reproductive success.

The observations described here were made as part of work for a documentary film series (Canarias, reductos de biodiversidad) on Canarian biodiversity conducted by Alas Cinematografía S.L. We thank Pedro Felipe and José J. Hernández for their invaluable help in the field, as well as Alfredo Valido, Rubén Barone, and Kimberly Holbrook for reviewing an early draft of the manuscript.

FELIPE SIVERIO (e-mail: felipe.siverio@telefonica.net), Alas Cinematografía S.L., Los Afligidos 43, 38410 Los Realejos, Tenerife, Canary Islands, Spain; **MARÍA C. RODRÍGUEZ-RODRÍGUEZ**, Integrative Ecology Group, Estación Biológica de Doñana (CSIC), Avda. Américo Vespucio s/n, 41013 Sevilla, Spain.

***GEHYRA AUSTRALIS* (Northern Dtella). PREDATION.** *Gehyra australis* is a variably patterned, ~81mm SVL, arboreal and rock-inhabiting gecko native to the northern reaches of the Northern Territory and Western Australia (Wilson and Swan 2010. A Complete Guide to Reptiles of Australia, 3rd ed. New Holland Publishers, Sydney). I am unaware of any reports of predation on *G. australis* by an arachnid. I report here an instance of predation on *G. australis* by the Grey Huntsman Spider (*Holconia immanis*).

On 2 May 2011, near the town of Wyndham in the eastern Kimberley region of Western Australia, I was performing daily checks of nest-boxes, specifically designed to be utilized by breeding Gouldian Finches (*Erythrura gouldiae*). These boxes consist of a natural log (ca. 20–40 cm long) attached to a 10 cm^2 plywood nesting box, which can be removed to investigate the contents. At 0746 h I came across a Grey Huntsman Spider in the process of subduing an adult *G. australis* in the anterior section of one of the aforementioned boxes (15.5704°S, 128.1892°E, 79 m elev.). The gecko was clearly still alive and was attempting to break free of the huntsman's grip. Upon removal of the box, the huntsman crawled out onto the box's exterior (Fig. 1), descended the tree in which the nest-box was situated, and withdrew into tall *Sorghum* grass with the gecko still in its grip. These two species are frequently observed cohabiting these boxes, but this was the first instance in which I, or any other members of the Save The Gouldian Fund, have encountered such a predation attempt.

DAVID G. HAMILTON, Save The Gouldian Fund, P.O. Box 340, Wyndham, 6740, WA, Australia; e-mail: davidghamilton@hotmail.com.

FIG. 1. *Holconia immanis* in the process of subduing an adult *Gehyra australis* near Wyndham, Western Australia.

***HEMIDACTYLUS FRENATUS* (Common House Gecko). PREDATION.** Many spiders feed on a variety of vertebrates such as small mammals, birds, and lizards (Corey 1988. J. Arachnol. 16:391–392; McCormick and Polis 1982. Biol. Rev. 57:29–58; Rubbo et al. 2001. Can. J. Zool. 79:1465–1471). On 20 August 2010, at 2015 h we encountered a predation event involving

FIG. 1. Predation of *Hemidactylus frenatus* by the spider *Heteropoda venatoria*.

Hemidactylus frenatus by the spider *Heteropoda venatoria* at Shahbajpur (24.7058°N, 92.1913°E) in Barlekha, Maulvibazar District, Bangladesh. The incident took place on the wall of a resident's house within a tea garden where the gecko was ambushed by the spider (Fig. 1). The struggle lasted for a period of ca. 20 min., after which the spider dropped the lizard and fled, most likely due to human interference.

***IGUANA IGUANA* (Green Iguana). COPROPHAGY.** *Iguana iguana* occurs from Mexico to Brazil as well as some Caribbean islands (Burghardt and Rand 1982. Iguanas of the World: Their Behavior, Ecology, and Conservation. Noyes Publications, New Jersey. 472 pp.). It is a largely arboreal (Iverson 1982. *In* Burghardt and Rand, *op. cit.*, pp. 60–76) and herbivorous species, eating mostly leaves, flowers, and fruits from a wide range of shrubs, vines, and trees (Rand et al. 1990. J. Herpetol. 24:211–214). The Green Iguana is reported to occasionally scavenge on animal carcasses (Loftin and Tyson 1965. Copeia 1964:515), as well as eating insects (Hirth 1963. Ecology 44:613–615), or other invertebrates (Fitch 1973. Univ. Kansas Sci. Bull. 50:39–126; Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna between Two Continents, between Two Seas. University of Chicago, Chicago, Illinois. 934 pp.). Consumption of bird eggs has also been reported (Schwartz and Henderson 1991. Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History. Univ. Florida Press, Gainsville, Florida. xvi+720 pp.). In Florida, where the Green Iguana is a well-established exotic species, the examination of stomach contents revealed remains of snails in two individuals, including 12 snails in one juvenile (Townsend et al. 2005. Southeast. Nat. 4:361–354).

Coprophagy is generally rare in reptiles, and usually involves eating the feces of other taxa (Frye 1991. Reptiles: An Atlas of Diseases and Treatment. TFH, Neptune City, New Jersey. 637 pp.). The Green Iguana utilizes a microbial fermentation system in its elaborated hindgut to break down plant cell walls (Mackie et al 2004. Physiol. Biochem. Zool. 77:127–138). Hatchlings have been observed to actively associate with adults during the first weeks of life and to consume fresh fecal material from adult iguanas to obtain the complex microflora (Werner et. al 1987. Behav. Ecol. Sociobiol. 21:83–89). In Galapágos Archipelago, Land and Marine Iguanas (*Conolophus pallidus* and *Ampblyrhynchus cristatus,* respectively) have been observed eating feces of crabs and sea lions, and it has been speculated that this is done in order to acquire microorganisms, mostly bacteria, to properly digest various plant chemicals (Mackie et al., *op. cit.*). In a long term study on the endangered Grand Cayman Blue Iguana (*Cyclura lewisi*), Goodman (2007. Carib. J. Sci. 43:73–86) reported the consumption of Central American Agouti (*Dasyprocta punctata*) feces on one occasion. We have found no references in the literature regarding free-living juvenile or adult Green Iguanas feeding on the feces of other animals other than conspecifics. We report here on coprophagy of Green Iguana adults and hatchlings eating feces from Giant Otter (*Pteronura brasiliensis*) latrines.

Giant Otters live in social groups and use latrines to mark their territory (Leuchtenberger and Mourão 2009. Ethology 115:210–216). In December of 2010, during a Giant Otter research trip on the Vermelho River (56.7333°W, 19.6000°S, WGS84; elev. 60 m), in the southern Pantanal, camera traps were positioned at three Giant Otter latrines. These cameras were active in 24-h cycles during three days at latrines 1 and 2, and just one day at latrine 3, resulting in a total of 509 photos of Green Iguanas. All of these photos were during the diurnal period and revealed that both juveniles and adults lizards consumed feces of the otters. The eight photos taken from latrine 1 were consistently of the same adult female, while the five photos from latrine 3 indicated two adult females and one adult male. Detailed examination of the 495 photos taken from latrine 2 indicated that there were at least eight adult females, one adult male, and two juveniles visiting that locale. Often the iguanas visited the latrines soon after the otters left the area. For example, in one case one photo registered eight female iguanas eating feces together, just 15 min. after the otter group had left that latrine (Fig. 1).

Giant Otters feed mainly on fish, and their spraints are usually deposited in latrines that are used by the whole group (Duplaix 1980. Rev. Ecol. 34:496–620). Therefore, the spraints containing fish bones and scales probably provide a rich source of calcium for this herbivorous lizard species. Most individuals identified in the photo images were adult females or juveniles which would all have high calcium requirements; adult females due to the production of eggs and juveniles for growth. It may also be speculated that fecal samples provide the reptiles with special microorganisms and bacteria as hypothesized by Mackie et al. (*op. cit.*).

FIG. 1. *Iguana iguana* females feeding at a Giant Otter (*Pteronura brasiliensis*) latrine on the Vermelho River, Southern Pantanal, Brazil.

Another interesting aspect of this behavior is that lizards usually aggregated to the otter latrines. Aggregation of adult female iguanas has been described during the reproductive period where they exhibited a communal nesting strategy, which is often described as an antipredator tactic (Mora 1989. Herpetologica 45:293–298). Group behavior of hatchlings has also been reported as an antipredator strategy (Green et al. 1978. J. Herpetol. 12:169–176).

The importance of coprophagy in the dietary supplementation of *Iguana iguana* is difficult to evaluate. However, this behavior can certainly be precarious for the lizards. While on the ground, the arboreal iguanas are more susceptible to predators and coprophagy facilitates the transmission of parasites from the otters to the iguanas.

***LAMPROLEPIS SMARAGDINA PHILIPPINICA* (Emerald Green Tree Skink). COLOR VARIATION.** *Lamprolepis smaragdina* is a widespread skink distributed throughout the Philippine Islands, eastern Indonesia, Papua New Guinea, and the islands of the West Pacific. This arboreal species is recognized to have a high degree of body color variation between populations (Mertens 1929. Zoologischer Anzeiger 84:209–220). One of three recognized subspecies, *L. s. philippinica* is endemic to the Philippine islands (Brown and Alcala 1980. Philippine Lizards of the Family Scincidae. Silliman University Press, Dumaguete City. 264 pp.; Mertens, *op. cit.*). Populations of *L. s. philippinica* range in color from green anteriorly and brown posteriorly, to mottled brown and black on a green ground color (Brown and Alcala, *op. cit.*). Outside of the Philippines, populations displaying a completely bright green body are known from the southern peninsulas of Sulawesi, Palau, the Solomon Islands, and the Marshall Islands (Buden 2007. Pacific Science, 61:415–428; Mertens, *op. cit.*). Here we report on the first records of green populations of Philippine *Lamprolepis*, discovered on the small, isolated islands of Caluya, in the west-central Philippines, and Siquijor, in the south-central Philippines.

In 1997, R. Brown and J. McGuire collected 12 specimens of a population of *L. s. philippinica* possessing bright green bodies with black rhomboid blotches on Siquijor Island in the south-central Philippines. Individuals were collected on 9 September 1997, on the trunks and small branches of trees, in two localities on Siquijor Island, Siquijor Province, Philippines (9.2°N, 123.5°E): (11 individuals) Barangay Kang-Adiang, Municipality of Siquijor; (one individual) Barangay Caitic, Municipality of La Arena. The specimens are deposited at the Texas Natural History Collections, University of Texas at Austin (TNHC 56434–65).

During recent fieldwork in the central Philippine islands, CDS collected five all green, adult *L. s. philippinica* (Fig. 1). The specimens were observed on 15 November 2004, in a mangrove swamp at sea level, on small branches of trees over water, in Barangay Tinogboc, Municipality of Caluya, Antique Province, Caluya Island, Philippines (11.93003°N, 121.54723°E, datum: WGS 84; elev. 0 m). The specimens are deposited at the herpetological collections of the Biodiversity Institute, University of Kansas (males: KU 302835–37; females: KU 302838, 302839).

CAMERON D. SILER (e-mail: camsiler@ku.edu) and **CHARLES W. LINKEM** (e-mail: cwlinkem@ku.edu), Department of Ecology and Evolutionary Biology, Natural History Museum and Biodiversity Institute, University of Kansas, Dyche Hall, 1345 Jayhawk Blvd, Lawrence, Kansas 66045-7561, USA.

***LIOLAEMUS GOETSCHI*. PREDATION.** *Liolaemus goetschi* is an oviparous and insectivorous, medium-sized lizard (max. SVL = 73 mm) inhabiting the arid landscape of Monte Desert in northern Patagonia, Argentina. Its geographic distribution ranges through a narrow strip in northwestern Rio Negro Province along the boundary with Neuquén Province (Nori et al. 2010. Check List 6:3–4). To our knowledge, no studies are available on the biology of this species, including its natural predators. Here we report an observation of *Philodryas psammophidea* predation on *L. goetschi*. *Philodryas psammophidea* is an uncommon snake, with a large geographic distribution within Monte and Chacoan environments of Bolivia, Paraguay, and Argentina.

At 1930 h on 5 December 2010 during a collecting trip through northern Rio Negro Province we observed an adult female *L. goetschi* (SVL = 72.9 mm) basking in an open area between bushes outside National Road 151, 50 km S Catriel, General Roca Department (38.283861°S, 67.996278°W, WGS 84; 551 m elev.). As we approached, the lizard ran to seek refuge below branches of a *Larrea nitida* bush. When it reached the proximity

of the bush, a *Philodryas* (female; SVL 600 mm, TL 738 mm) appeared between the branches and chased the lizard for 3–4 m. It grabbed the lizard by its left forelimb and coiled around the lizard's body. We immediately grabbed the snake and forced it to release the lizard; it continued its grasp to the left forelimb with its mouth. After a minute of handling, the snake finally released the lizard. The *Liolaemus* was motionless after being released from the snake's grasp and did not appear to be alive. Two fang puncture wounds were evident in its leg and it likely died from envenomation. The specimens of *L. goetschi* (LJAMM-CNP 13731) and *Philodryas psammophidea* (LJAMM-CNP 13732) were deposited in the herpetological collection Luciano Javier Avila Mariana Morando of the Centro Nacional Patagónico – CONICET, Puerto Madryn, Argentina.

LUCIANO JAVIER AVILA (e-mail: avila@cenpat.edu.ar) and **CRISTIAN HERNAN FULVIO PEREZ**, CENPAT-CONICET, Boulevard Almirante Brown 2915, U9120ACD, Puerto Madryn, Chubut, Argentina.

***LIOLAEMUS QUILMES*. ULTRAVIOLET COLORATION**. *Liolaemus quilmes* is a liolaemid lizard from northwestern Argentina. It belongs to a genus of more than 223 species (Lobo et al. 2010. Zootaxa 2549:1–30) distributed throughout most of southern South America. Because *Liolaemus* species go from dull to bright coloration, they offer a model system for studies in visual communication (e.g., Font et al. 2010. Acta Zool. Lilloana 54:11–34; Fox et al. [eds.] 2003. Lizard Social Behavior. Johns Hopkins Univ. Press, Baltimore and London. 456 pp.). Some species of *Liolaemus* present blue-colored spots (e.g., those belonging to the *darwinii* complex of which *L. quilmes* is a member; Etheridge 1993. Bolletino Museo Regionale di Scienze Naturali, Torino 11:137–199), which in some lizards has been shown to be associated with ultraviolet coloration (UV, corresponding to wavelengths below 400 nm). This coloration and the ability to perceive it has been reported in more than 30 lizard species (Font et al. 2010, *op. cit.*) but it has not been studied in *Liolaemus*. Male *L. quilmes*, and females, to a lesser degree, exhibit blue spots, mostly on the lateral sides of their body (Etheridge 1993, *op. cit.*), which we hypothesized could indicate the presence of UV coloration.

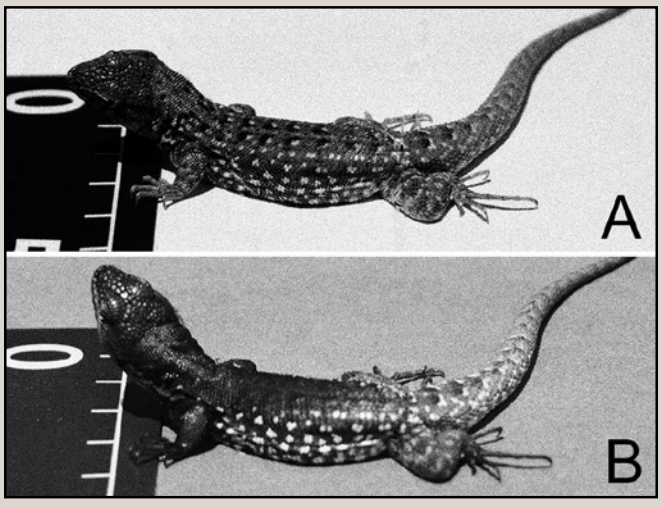

FIG. 1. Male *Liolaemus quilmes*: A) black and white picture taken without a UV filter (light white spots correspond to blue spots when seen by a human); B) black and white picture taken with a UV filter, showing brighter white spots where blue spots were, indicating UV reflectance.

We photographed live specimens of *L. quilmes* (2 males and 1 female) in their habitat, in Los Cardones, Tucumán, using a relatively simple method to confirm presence of UV coloration. Photographs were taken around noon, using natural sunlight. We first took a standard black and white photo with an analog camera (Canon EOS Rebel G), which was then compared to a second photo taken with the same camera and a filter B+W 403. This allowed only wavelenghts between 320 and 385 nm to pass through the filter, blocking the rest of the visible light spectrum.

We found that *L. quilmes* does reflect UV light corresponding to areas with light blue spots, this being the first report for a species in this genus (Fig. 1A, B). We then photographed live specimens of five congeners from Mendoza, Argentina, using the same method. These were *L. darwinii* (1 male), *L. grosseorum* (4 males), and *L. gracilis* (1 female), from El Nihuil, and *L. ruibali* (5 males and 1 female) and *L. bibroni* (1 male and 1 female) from Cruz de Paramillo. All of the individuals that were photographed reflected UV light except for those belonging to *L. gracilis* and *L. bibroni*. The latter two species are light to dark brown in coloration, explaining the lack of UV reflectance, whereas the other three species display blue spots, among other coloration. Our results open the opportunity for comparative research in the genus *Liolaemus* with respect to presence/absence of UV coloration and its communicative role within the behavioral ecology of each species (Fox et al. 2003, *op. cit.*; Font et al. 2010, *op. cit.*).

We thank Cecilia Robles, Cristian Abdala, and Romina Semhan for help in the field. Financial support was provided by Fundación Miguel Lillo, PIP-CONICET 2422 and CIUNT G430.

MARÍA JOSÉ SALICA (e-mail: mjsalica@gmail.com) and **MONIQUE HALLOY** (e-mail: mhalloy@webmail.unt.edu.ar), Instituto de Herpetología, Fundación Miguel Lillo, Miguel Lillo 251, 4000 San Miguel de Tucumán, Argentina.

***MESASPIS GADOVII* (Gadow's Alligator Lizard). REPRODUCTION.** *Mesaspis gadovii* is known from parts of Guerrero and Oaxaca, Mexico (Flores Villela and Gerez 1994. Biodiversidad y Conservacíon en México: Vertebrados, Vegetacíon y Uso del Suelo. Univ. Nac. Auton. Mexico, D.F., México, 439 pp.). Ramírez-Pinilla et al. (2009. J. Herpetol. 43:409–420) reported a mean litter size of 7.3 ± 1.9 SD, range = 4–12 for 16 females of *M. gadovii* from Guerrero. The smallest reproductively active female (vitellogenic follicles) measured 76 mm SVL (Ramirez-Pinilla, *op. cit.*). The purpose of this note is to report a new minimum litter size and minimum size for female reproduction of *M. gadovii*.

One *M. gadovii* female (SVL = 73 mm) collected on December 1971 in the Sierra Madre del Sur, (17.5000°N, 100.0000°W, WGS 84; elev. ca. 1000 m), Guerrero, Mexico, and deposited in the herpetology collection of the Natural History Museum of Los Angeles County (LACM), Los Angeles, California as LACM 75504 was examined. A midventral slit was made and the reproductive system was examined. Two embryos were present. A litter size of two is a new minimum litter size, and the SVL of 73 mm is a new minimum body size for female reproductive activity in *M. gadovii*.

I thank Christine Thacker (LACM) for permission to examine *M. gadovii*.

STEPHEN R. GOLDBERG, Department of Biology, Whittier College, Whittier, California 90608, USA; e-mail: sgoldberg@whittier.edu.

***OPHISAURUS VENTRALIS* (Eastern Glass Lizard). POSTMORTEM PREDATION.** Although several hawk species have been documented or implicated as predators of glass lizards (genus

PHOTO BY F. CLARKE

FIG. 1. Loggerhead Shrike (*Lanius ludovicianus*) with body segment of an Eastern Glass Lizard (*Ophisaurus ventralis*) held in its bill.

Ophisaurus; Fitch 1974. Condor 76:331–360; Fitch and Bare 1978. Trans. Kansas Acad. Sci. 81:1–13), we are aware of no other bird species reported to consume them. On 17 February 2010 at Skidaway Island, Chatham Co., Georgia, USA (31.95652°N, 81.02442°W), one of us (FOC) observed a Loggerhead Shrike (*Lanius ludovicianus*) fly down to a recently mowed berm along a weedy field, pick up a flexible and tubular item, fly back to its perch, and begin consuming this item. Photographs taken by FOC of this bird while back on its perch were shared with JBJ and JAC who positively identified the item as a body segment of an Eastern Glass Lizard (*Ophisaurus ventralis*) (Fig. 1). It is suspected that the glass lizard was killed (likely by the mowing activities) prior to its seizure by the shrike. The time it took for the shrike to fly from its perch and return with the motionless food item was estimated to be just 15–20 seconds. Although predation cannot be conclusively ruled out, the short duration of capture time, coupled with likelihood that a fully intact and live sub-adult or adult Eastern Glass Lizard would be too large for a shrike to attack, suggests it was seized postmortem. Although legged lizards have been reported in the diet of Loggerhead Shrikes (Yosef 1996. *In* Poole and Gill [eds.]. The Birds of North America, No. 231. Acad. Nat. Sci., Philadelphia, and Amer. Ornithologists' Union, Washington, D.C.), insofar as we can determine, this is the first reported observation of a Loggerhead Shrike consuming as carrion, or predating, any species of glass lizard.

FITZ O. CLARKE, 6 Middleton Road, Savannah, Georgia 31411, USA (e-mail: fitzclarke@bellsouth.net); **JOHN B. JENSEN**, Georgia Department of Natural Resources, Nongame Conservation Section, 116 Rum Creek Drive, Forsyth, Georgia 31029, USA (e-mail: john.jensen@gadnr.org); **JOHN A. CRAWFORD,** University of Georgia Marine Extension Service, 30 Ocean Science Circle, Savannah, Georgia 31411, USA (e-mail: crawfish@uga.edu).

***PLESTIODON SUMICHRASTI* (Sumichrast's Skink). PREDATION.** There are many reports of large tropical spiders preying upon amphibians and reptiles (e.g., Antônio de Freitas et al. 2010. Herpetol. Rev. 41:202; Brito De-Carvalho et al. Herpetol. Rev. 2010. 41:336–337; Cicchi et al. 2010. Herpetol. Rev. 41:207; Hamidy et al. 2010. Herpetol. Rev. 41:66–67). Although many of these reports document predation on small frogs and lizards (< 4 cm SVL), larger prey items are occasionally taken or attempted (e.g., Silva Siqueira Nunes et al. 2010. Herpetol. Rev. 41:367–368). Here we report an instance of a relatively large lizard as a prey item for a tarantula from the highlands of southeastern Guatemala.

FIG. 1. Predation of *Plestiodon sumichrasti* (top) by *Brachypelma* sp. (bottom) in the Sierra Caral of Izabal, Guatemala.

On 2 October 2010 we were conducting a herpetofaunal survey in the Sierra Caral of Izabal, Guatemala. At approximately 1800 h while pulling apart a large fallen tree trunk, we discovered a cavity that contained a partially digested juvenile *Plestiodon sumichrasti* (ca. 6 cm SVL; Fig. 1 [top]). Further excavation immediately behind the partially digested lizard revealed a large male tarantula referable to the genus *Brachypelma* (Fig. 1 [bottom]). This observation occurred near Cerro Pozo de Agua at about 850 m (15.39367°N, 088.69183°W; WGS84 datum). The slightly dissolved skink was collected and deposited in the natural history collections of the Museo de Historia Natural of the Universidad de San Carlos in Guatemala City (USAC 2738; Field ID: CRVA 2162).

We thank Mónica Barrientos, Obdulio Javier Villagran, Eric N. Smith, and FUNDAECO for field and logistical assistance. Chris A. Hamilton and his colleagues kindly helped with tarantula identification. This observation was made while conducting field work supported by Conservation International. Scientific collecting permits were issued by Consejo Nacional de Areas Protegidas ([CONAP]; 030/2010 to E. N. Smith, and 008/2010, 12809 to C.R. Vásquez-Almazán).

VÁSQUEZ-ALMAZÁN** (e-mail: crvasal@yahoo.com.mx), Museo de Historia Natural, Escuela de Biología, Universidad de San Carlos, Ciudad de Guatemala, Guatemala.

***SAUROMALUS ATER* (Common Chuckwalla). ENTRAPMENT.** On 31 May 2008, we found an adult male *Sauromalus ater* dead in tortoise mitigation fencing along U.S. Highway 93, 1.0 km NW of Nothing, Mohave Co., Arizona, USA (34.48279°N, 113.35129°W, WGS84; elev. 965 m). The fence, originally intended to keep Desert Tortoises (*Gopherus agassizii*) off of the highway and direct them towards highway underpasses, is 60 cm in height, with galvanized mesh fabric (2.5 cm × 5 cm). The chuckwalla was caught between its rib cage and front legs at ground level probably as it tried to move through the fencing (Fig. 1). Use of fencing to modify animal movements away from roads should consider impacts to other small animals that may get stuck and die from starvation or exposure (Sherwood et al. 2002. Wildlife and Roads: The Ecological Impact. Imperial College Press, London. 316 pp.). One possible solution for this source of mortality would be to modify the fence mesh size at the bottom, however any modifications could change the level of hazard for other animals and affect the fence's effectiveness in preventing focal species from moving across the highway.

NICHOLE E. BLODGETT and **DAVID D. GRANDMAISON**, Arizona Game and Fish Department, 5000 W. Carefree Highway, Phoenix, Arizona 85086, USA (e-mail: dgrandmaison@azgfd.gov).

FIG. 1. An adult male *Sauromalus ater* trapped in mitigation fencing for Desert Tortoises (*Gopherus agassizii*), resulting in its death.

***SCELOPORUS GRAMMICUS* (Mesquite Lizard). DIET.** Feeding is one of the most important aspects in the life history of amphibians and reptiles (Stearns 1977. Ann. Rev. Ecol. Syst. 8:145–171). It is well known that most reptile species are carnivores and omnivores. However; if they have the opportunity, many reptiles will feed on dead prey (carrion). Scavengery has been observed in lizards such as *Varanus panoptes* from Australia (Shine 1986. Herpetologica 42:346–360) and *Leiocephalus psammodromus* (Iverson and Smith 2006. Herpetol. Rev. 37:345–346). Within the genus *Sceloporus, S. grammicus* is particularly known for being insectivorous (Leyte-Manrique et al. 2006. Bol. Soc. Herpetol. Mex. 1:18–24) and Leyte-Manrique et al. (2005. Herpetol. Rev. 36: 454–455) reported cannibalism. However, to our knowledge, until now nothing has been reported on this species being a carrion-eater.

On 15 April 2008 at 1230 h, during a field trip to La Manzana, Zimapan (20.87056°N, 99.22417°W, WGS84; elev. 2531 m), Hidalgo, México, we observed an adult female *Sceloporus grammicus* (SVL = 52.6 mm, 6.0 g) in a crevice eating a female *S. minor* (SVL = 68.6 mm, 10.2 g). This observation suggests that *S. grammicus* could have opportunistic feeding habits. Moreover, a previous study reported that this *S. grammicus* eats neonates of its own species (Leyte-Manrique et al. 2005. Herpetol. Rev. 36:454–455) and skin of adult lizards (probably *S. spinosus;* Leyte-Manrique 2007. Bol. Soc. Herpetol. Mex. 15:23–24).

Both specimens (ZIMAPABR2-2008 and HAZIMAPSM-ABR1-2008) are deposited in the Laboratorio de Ecología de Poblaciones del Centro de Investigaciones Biológicas (CIB), de la Universidad Autónoma del Estado de Hidalgo.

Thanks to V. Mata-Silva for his logistic help. We thank C. Serrano and O. Barrera for field assistance, and the people of the town La Manzana, Zimapan for their help. This study was supported by the projects CONACYT-S 52552-Q and FOMIX-CONACYT-43761.

ADRIAN LEYTE-MANRIQUE (e-mail: aleyteman@gmail.com), **GUSTAVO RIVAS-GRANADOS** (e-mail: rivas_gusbiologia@yahoo.com.mx), and **AURELIO RAMÍREZ-BAUTISTA** (e-mail: aurelior@uaeh.edu.mx), Centro de Investigaciones Biológicas (CIB), Universidad Autónoma del Estado de Hidalgo, A.P. 1-69 Plaza Juárez, C.P. 42001, Pachuca, Hidalgo, México.

***SCELOPORUS MINOR* (Minor Spiny Lizard). HERBIVORY.** Herbivory in lizards has been well documented (Cooper et al. 1990. Herpetologica. 29:107–110). However, there are some species that display more than one feeding behavior, both insectivory and herbivory (omnivory) such as *Ctenosaura pectinata* (Durtsche. 2000. Oecología. 89:85–195) and *Tropidurus etheridgei* (Ávila et al. 2008. Herpetol. Rev. 39:430–433). Some species of the genus *Sceloporus* have been observed to feed on fruits, seeds and flowers, such as *S. torquatus* (Búrquez et al. 1986. J. Herpetol. 20:262–264). However, other species of this genus are thought to be completely insectivorous (Uribe-Peña et al. 1999. Anfibios y Reptiles de las Serranías del Distrito Federal, México. UNAM. 119 pp). The diets of many *Sceloporus* species remain poorly known in México. Herein, we provide information suggesting that one of these species, *S. minor,* has an omnivorous feeding behavior.

On 26 April 2008 at 1114 h at the locality of El Enzuelado, 7 km N of the Municipality of San Agustín Meztquititlán (20.57500°N, 98.62028°W, WGS84; elev. 1940 m), Hidalgo, México, we observed an adult male *S. minor* (SVL = 65.7 mm; 14.0 g) perching on a rock (26 cm high) within a xeric scrub community. We noticed that the lizard was eating the fruit of a cactus (163.1 mm^3; 0.0552 g; *Mammillaria* sp.); this fruit is locally known as *chilitos.* The fruit was eaten by the lizard within 15–20 seconds. After this feeding event, the lizard was captured and taken to the laboratory and later deposited in the Laboratorio de Ecología de Poblaciones del Centro de Investigaciones Biológicas (CIB), Universidad Autónoma del Estado de Hidalgo (SAM-ABR3-2008). This observation expands our knowledge about the diet of *S. minor,* possibly indicating this species is omnivorous and this opportunistic foraging provides evidence that *S. minor* may take advantage of chilitos as a food resource when available.

We thank Gustavo Rivas for his logistic help and the people from the community of El Enzuelado, San Agustín Metzquititlán

for their help during the field work. This study was supported by the following projects: PIFI-PROMEP 3.3. 2007, CONACYT-S 52552-Q, and FOMIX-CONACYT-43761.

***SCINCELLA REEVESII* (Reeves' Smooth Skink). REPRODUCTION.** *Scincella reevesii* is known from Vietnam, India, southern China, Korea, Thailand, and Malaysia (Van Sang et al. 2009. Herpetofauna of Vietnam. Edition Chimaira, Frankfurt am Main, Germany.768 pp.). *Scincella reevesii* is ovoviviparous with litters of 2–3 young born in late spring (Karsen et al. 1986. Hong Kong Amphibians and Reptiles. Published by the Urban Council, Hong Kong. 136 pp.). The purpose of this note is to report a new maximum litter size for *S. reevesii*.

One female *S. reevesii* (SVL = 48 mm) collected 12 June 1993 from Hong Kong, China (Port Shelter, Yim Tin Tsai (22.410278°N, 114.215556°E, datum WGS84; elev. 10 m) and deposited in the Museum of Comparative Zoology (MCZ) as MCZ R-177979 was examined. The posterior third of the body cavity was opened and four embryos were counted. Four is a new maximum litter size for *S. reevesi*.

I thank Jonathan Losos (MCZ) for permission to examine *S. reevesii* and Jose Rosado (MCZ) for facilitating the loan.

STEPHEN R. GOLDBERG, Department of Biology, Whittier College, Whittier, California 90608, USA; e-mail: sgoldberg@whittier.edu.

***SCINCELLA REEVESII* (Reeves' Smooth Skink). ENDOPARASITES.** *Scincella reevesii* is known from Vietnam, India, southern China, Korea, Thailand, and Malaysia (Van Sang et al. 2009. Herpetofauna of Vietnam, Edition Chimaira, Frankfurt am Main, Germany. 768 pp.). To our knowledge, there are no reports of helminths from *S. reevesii*. The purpose of this note is to establish the initial helminth list for *S. reevesii*.

Twenty *S. reevesii* from Hong Kong, China (mean SVL = 42.3 mm ± 5.5 SD, range = 30–52 mm) collected 1991–1994, 1996, were borrowed from the herpetology collection of the Museum of Comparative Zoology (MCZ): (MCZ) R-176657–17663, 176666–176669; 177083, 177977, 177979–177981, 179465, 17946, 179482, 182293.

The body cavity was opened and the digestive tract was removed, opened by a longitudinal incision, and examined under a dissecting microscope. Nematode larvae in cysts were found in the stomach wall and supportive mesenteries, which were cleared in lacto phenol solution, placed on a glass microscope slide, cover-slipped and identified as Acuariidae gen. sp. Prevalence (infected lizards/all lizards x100) was 20%; mean intensity (mean number helminths per lizard) was 2.0 ± 1.4 SD, range = 1–4. They were deposited in the invertebrate collection at MCZ as IZ-124533–124536.

Members of the Acuariidae are gizzard parasites of terrestrial birds; insects serve as intermediate hosts (Anderson 2000. Nematode Parasites of Vertebrates: Their Development and Transmission, 2nd ed. CABI Publishing, Wallingford, Oxfordshire, U.K. 650 pp.). Their occurrence in lizards likely results from ingesting infected insects; no further development occurs (Goldberg et al. 2002. Amer. Midl. Nat. 148:409–415). The occurrence of Acuariidae in amphibians and reptiles is summarized in Goldberg et al. (2007. Comp. Parasitol. 74:327–342). *Scincella reevesii* represents a new host record for larvae of the Acuariidae.

We thank Jonathan Losos (MCZ) for permission to examine *S. reevesii* and Jose Rosado (MCZ) for facilitating our loan.

STEPHEN R. GOLDBERG, Department of Biology, Whittier College, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu); **CHARLES R. BURSEY,** Department of Biology, Pennsylvania State University, Shenango Campus, Sharon, Pennsylvania 16146, USA (e-mail: cxb13@psu.edu).

***TUPINAMBIS MERIANAE* (Black-and-White Tegu). NEST CONSTRUCTION BEHAVIOR.** *Tupinambis merianae* is one of the largest lizard species indigenous to the New World. There is little information published on the ecological aspects within natural environments for this genus. Daily and annual activity for *T. merianae* have been reported for an Atlantic Rainforest area in Southeastern Brazil (Van Sluys and Rocha. 1999. Herpetol. Rev. 30:42–43). Recently the hibernation and emergence behavior of a natural population in Southern Brazil were described (Winck and Cechin. 2008. J. Nat. Hist. 42:239–247). Oviposition inside burrows is known, including the importance of the presence of the female to the eggs during their development (Chani et al. 1994. Acta Zool. Lilloana 42:295–299). However, ecological aspects related to nest construction remains unknown in natural populations.

On 5 December 2005, during the study of ecological aspects of a population of *T. merianae*, we witnessed an adult female (366 mm SVL; 1.9 kg) preparing its burrow for oviposition in sandy soil. The observation was made at Taim Ecological Station (Estação Ecológica do Taim), municipality of Santa Vitória do Palmar, State of Rio Grande do Sul, Brazil (32.836944°S, 52.643889°W). By palpation, we confirmed the presence of eggs. About two days before laying the eggs, the female had started to collect vegetation material around the burrow. Positioned with her back to the burrow opening, her movements were recorded chronologically as follows: 1) the female moved plant matter towards her belly to the pelvic girdle with her forelimbs; 2), then pushed the vegetation with its hind limbs until the full extension of the limbs was reached; 3) the lizard then turned around and pushed the pile of plant matter with its forelimbs into the interior of the burrow. We were not able to see how the vegetation was arranged inside, as the lizard entered the burrow and we opted to avoid disturbance. On 19 December 2010, GRW observed a similar behavior displayed by an adult female of a similar body size of that from the Taim site, in the municipality of São João da Barra (Grussaí restinga habitat), State of Rio de Janeiro, Brazil (21.737778°S, 41.034722°W). The nest at Grussaí was also constructed on the ground in sandy soil. The vegetation is likely to assist in the manipulation of internal temperatures of the burrow. These localities are more than 1600 km apart, suggesting that this nest construction behavior may be related to the natural history of the species, rather than a behavioral adaptation to a particular environment.

GISELE REGINA WINCK, Departamento de Ecologia, Universidade do Estado do Rio de Janeiro, Rua São Francisco Xavier 524, Maracanã, 20541-000, Rio de Janeiro – RJ, Brazil (e-mail: gwinck@yahoo.com.br); **SONIA ZANINI CECHIN**, Departamento de Biologia, Centro de Ciências Naturais e Exatas, Universidade Federal de Santa Maria, Av. Roraima s/n, Camobi, 97150-900, Santa Maria – RS, Brazil; **CARLOS FREDERICO DUARTE ROCHA**, Departamento de Ecologia, Universidade do Estado do Rio de Janeiro, Rua São Francisco Xavier 524, Maracanã, 20541-000, Rio de Janeiro – RJ, Brazil.

***UROSTROPHUS VAUTIERI* (Brazilian Steppe Iguana). DEFENSIVE BEHAVIOR AND COLOR CHANGE.** *Urostrophus vautieri* occurs in southeastern Brazil, from Paraná to Rio de Janeiro State. Basic behavioral information for the genus *Urostrophus* is limited to unpublished notes made on one captive animal by Rand (*In* Etheridge and Williams 1991. Bull. Mus. Comp. Zool. 152:317–361). Herein, we describe the first field observation of defensive behavior for this lizard species.

On 11 November 2010, at Serra do Japi Municipal Reserve, Jundiaí, São Paulo state (23.235°S, 46.935°W; WGS 1984; elev ca. 1092 m. At 0936 h). The lizard was observed during a behavioral study of a group of Black-fronted Titi Monkeys (*Callicebus nigrifrons*) conducted in a semi-deciduous secondary forest area. The lizard fell onto the leaf litter from its arboreal perch in front of CBC, just before being contacted by a group of *Callicebus nigrifrons* travelling towards it. It fell off a fructifying *Maytenus robusta* branch at a height of approximately 8 m. Immediately after reaching the ground, its color gradually changed from a grayish green to a reddish brown (Fig. 1). The color change clearly diminished the lizard's conspicuous form on the forest floor. The lizard remained immobile for at least five min, until CBC was no longer present.

This is the second report on behavioral ecology of *Urostrophus vautieri* and the first on color change. We provide a first context for color change in this species regarding potential predation avoidance. The specimen was not captured or manipulated for photographs, as collection inside of the Reserve is prohibited without permits.

AGUSTIN CAMACHO GUERRERO, Laboratório de Herpetologia, Departamento de Zoologia, Instituto de Biociências, Universidade de São Paulo, Caixa Postal 11.461, CEP 05422–970, São Paulo, SP, Brazil (e-mail: agus.camacho@gmail.com); **CHRISTINI BARBOSA CASELLI**, Departamento de Biologia Animal, Instituto Biologia, Universidade Estadual de Campinas, Caixa Postal 6109, CEP 13083-970, Campinas, São Paulo, Brazil (e-mail: ccaselli@gmail.com).

FIG. 1. Color change in *Urostrophus vautieri*. Image at left taken immediately after lizard fell onto leaf litter from an arboreal perch. Image at right taken approximately 2 min later, indicating rapid color change toward substrate matching.

SQUAMATA — SNAKES

***ARIZONA ELEGANS ELEGANS* (Kansas Glossy Snake). DIET.** Medium-sized diurnal lizards comprise a large proportion of the diet of *Arizona elegans* (Rodriguez-Robles et al. 1999. J. Herpetol. 33:87–92). Rodriguez-Robles et al. (*op. cit.*) suggest that diurnal lizards may be captured "when they are inactive by nocturnal wide-foraging glossy snakes." Here we document the first record of *A. e. elegans* feeding on *Sceloporus cautus*, a lizard that is distributed in Mexico from the northeastern section of the Mexican plateau, west from the western edge of the Sierra Madre Oriental, barely entering Tamaulipas, and south from southwestern Coahuila and central Nuevo Leon to the southern portion of San Luis Potosi and northern half of Zacatecas (Lemos-Espinal and Smith 2007. Amphibians and Reptiles of the State of Coahuila, Mexico. Universidad Nacional Autónoma de México and Comisión Nacional Para El Conocimento y Uso de La Biodiversidad. 550 pp.).

While conducting a survey of the herpetofauna of the municipality of Doctor Arroyo, Nuevo Leon, Mexico, driving on state road No. 61 (23.8094°N, 100.0853°W, datum NAD27; elev. 1791 m), on 12 September 2009, we found a road-killed juvenile *A. e. elegans* (female; SVL = 202 mm, total length = 233 mm; 4.19 g), that had in its stomach a juvenile *Sceloporus cautus* (female; SVL = 35 mm; total length = 60 mm; 1.57 g); the lizard represented 37.5% of the mass of the snake. As *A. elegans* is nocturnal and *S. cautus* is diurnal, the lizard was likely captured while inactive. Both specimens were deposited in the herpetological collection of the Universidad Autonoma de Nuevo Leon (*A. e. elegans* = UANL 7128a; *S. cautus* = UANL 7128b). Research and collecting were conducted under the authorization of SEMARNAT scientific research permits OFICIO/NUM/SGP/DGVS/ 02262 issued to DL.

DAVID LAZCANO, Universidad Autónoma de Nuevo León, Facultad de Ciencias Biológicas, Laboratorio de Herpetología, Apartado Postal-513, San Nicolás de los Garza, Nuevo León, C.P. 66450, México (e-mail: dlazcanov@hotmail.com); **JERÓNIMO ALEJANDRO CHÁVEZ-CISNEROS**, Universidad Autónoma de Nuevo León, Facultad de Ciencias Biológicas, Laboratorio de Herpetología, Apartado Postal-513, San Nicolás de los Garza, Nuevo León, C.P. 66450, México; **JAVIER BANDA-LEAL**, Universidad Autónoma de Nuevo León, Facultad de Ciencias Biológicas, Laboratorio de Herpetología, Apartado Postal-513, San Nicolás de los Garza, Nuevo León, C.P. 66450, México.

***ASTHENODIPSAS MALACCANUS* (Malayan Slug Snake). DIET.** *Asthenodipsas malaccanus* is a rare lowland forest snake from southern Thailand, the Malay Peninsula, Sumatra, and Borneo (David and Vogel 1996. The Snakes of Sumatra. An Annotated Checklist and Key with Natural History Notes. Chimaira, Frankfurt am Main. 260 pp.). Its diet has been reported to consist of snails and slugs (Inger and Stuebing 1999. A Field Guide to the Snakes of Borneo. Natural History Publications [Borneo] Sdn Bhd, Kota Kinabalu. 254 pp.), without specific information. At ca. 2130 h on 19 September 2010, an adult female *A. malaccanus* (SVL = 357 mm; Fig. 1) was found crossing a paved road within lowland forest (01.6061°N, 110.1955°E, datum: WGS84; elev. ca. 200 m), leading to the summit of Gunung Serapi (elev. 911 m), in Kubah National Park, Sarawak, East Malaysia. The snake was collected (Universiti Malaysia Sarawak Museum, UNIMAS 9379), and taken to the lab. Overnight, it voided an intact slug (RMNH MOL.127788), which was identified as *Valiguna flava* (Gastropoda: Soleolifera: Veronicellidae; Fig. 1), a nocturnal/crepuscular lowland (elev. < 1000 m) terrestrial slug, endemic to Sumatra and Borneo (Gomes et al. 2008. The Veliger 50:163–170; Schilthuizen and Liew 2008. Basteria 72:287–306).

We thank Sarawak Forest Department for permission to conduct fieldwork at Kubah National Park.

INDRANEIL DAS, Institute of Biodiversity and Environmental Conservation, Universiti Malaysia Sarawak, 94300 Kota Samarahan, Sarawak, Malaysia (e-mail: idas@ibec.unimas.my); **MENNO SCHILTHUIZEN**, National

Museum of Natural History, 'Naturalis,' P.O. Box 9517, 2300 RA Leiden, The Netherlands (e-mail: menno.schilthuizen@ncbnaturalis.nl) and Institute for Tropical Biology and Conservation, Universiti Malaysia Sabah, Locked Bag 2073, 88999 Kota Kinabalu, Malaysia.

***BOTHROPS ASPER* (Terciopelo). ARBOREAL BEHAVIOR.** *Bothrops asper* is a common, large (up to 2.5 m total length), viperid snake ranging from southern Mexico to northern Venezuela and western Ecuador. Like many vipers, it is an ambush predator, remaining motionless in leaf litter for the majority of its activity budget and moving nocturnally to new ambush spots (Sasa et al. 2009. Toxicon 54:904–922). Although *B. asper* is typically regarded as a terrestrial snake (Henderson and Hoevers 1977. Copeia 1977:349–355), accounts of juveniles in low vegetation have been reported (Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna between Two Continents, between Two Seas. Univ. Chicago Press, Chicago, Illinois. 934 pp.; Guyer and Donnelly 2005. Amphibians and Reptiles of La Selva. Univ. California Press, Berkeley. 298 pp.) There are a few cases, however, of adults being observed in trees or other vegetation (Guyer and Donnelly, *op. cit.*). Here, we report a sighting of an adult *B. asper* in low-lying vegetation in central Panama.

FIG. 1. An adult *Bothrops asper* found in understory vegetation in El Copé, Panama.

At 1927 h, on 6 September 2010, we observed an adult (ca. 1.5 m total length) *B. asper* at a height of 2 m in a cluster of small understory trees (Fig. 1) at La MICA Biological Station, El Copé, Panama (8.374224°N, 80.345024°W, datum: WGS 84; elev. ca. 300 m). The *B. asper* attempted to cross a path by traversing a thin branch, but failed to do so. At 1955 h the snake left the vegetation and returned to the ground having moved a net horizontal distance of <2 m since the beginning of the observation. Because the snake was outstretched and moving, it seems that the purpose of ascending the vegetation was dispersal rather than ambush site selection. Sasa et al. (*op. cit.*) found that the majority of *B. asper* movements are short-range (<10 m), but that less frequently, longer-range movements (>50 m) related to foraging behavior also take place. This observation supports the idea that adult *B. asper* occasionally engage in arboreal behavior for various reasons.

We thank J. Knight, K. Knight, S. Mullin and the EIU Herpetology Lab, and especially the staff at La MICA Biological Station for their assistance, in and out of the field.

KYLE A. BAUMGARTNER, Department of Biological Sciences, Eastern Illinois University, Charleston, Illinois 61920, USA (e-mail: kabaumgartner@eiu.edu); **JULIE M. RAY**, La MICA Biological Station, El Copé de La Pintada, Coclé Province, Republic of Panama (e-mail: julie.ray@lamica.org)

***CANDOIA ASPERA* (New Guinea Ground Boa). REPRODUCTION.** *Candoia aspera* is known from New Guinea and adjacent island archipelagos (McCoy 2006. Reptiles of the Solomon Islands. Pensoft, Sofia, Bulgaria. 147 pp.). In Papua New Guinea it occurs from 0–1300 m elevation (O'Shea 1996. A Guide to the Snakes of Papua New Guinea. Independent Publishing, Port Moresby. 239 pp.). Current information on *C. aspera* reproduction is reported by Harlow and Shine (1992. J. Herpetol. 26:60–66). The purpose of this note is to provide additional information on the reproductive cycle of *C. aspera*.

Eight male *C. aspera* (mean SVL = 451 mm ± 51.8 SD, range: 373–515 mm) and four females (mean SVL = 604 mm ± 148.7 SD) collected between1986–2007 from Papua New Guinea and deposited in the herpetology collection of the Bernice P. Bishop Museum (BPBM), Honolulu, Hawaii, were examined: BPBM 18932, 12174, 23168, 23436, 23437, 23439, 23440, 27338, 28282, 30797, 31321, 31323. The left testis was removed from males and the left ovary was removed from females for histological examination. Slides were stained with Harris hematoxylin followed by eosin counterstain. Slides of testes were examined to determine the stage of the spermatogenic cycle. Slides of ovaries were examined for the presence of yolk deposition and/or corpora lutea. Enlarged ovarian follicles (>10 mm) were counted. Histology slides were deposited in the BPBM.

Two stages were noted in the male cycle: 1) spermiogenesis (sperm production) in which the lumina of the seminiferous tubules are lined by sperm or clusters of metamorphosing spermatids; 2) regression in which the germinal epithelium is greatly reduced and contains primarily spermatogonia and interspersed Sertoli cells. Some residual sperm from the last period of spermiogenesis may remain. Monthly samples of males exhibited the following stages of the testicular cycle: February (N =1) regressed; May (N = 2) regressed, (N = 1) spermiogenesis; August (N = 2); September (N = 1); October (N = 1) all spermiogenesis. These data suggest there is seasonality in the testicular cycle of *C. aspera* as has also been reported for the congener *C. carinata* (Wynn and Zug 1985. The Snake 17:15–24.).

One female *C. aspera* each from February, May, and September contained quiescent ovaries with no yolk deposition. One female from August contained nine enlarged ovarian follicles (> 10 mm). The presence of three non-reproductive females may suggest seasonality in the ovarian cycle of *C. aspera* or that not all females reproduce annually as suggested by Harlow and Shine (*op. cit.*). Less than annual production of young by *C. aspesa* was also indicated in Parker (1982. The Snakes of Western Province. Widl. Papua New Guinea 82:1–78).

I thank Pumehana Imada (BPBM) for facilitating my examination of *C. aspera.*

STEPHEN R. GOLDBERG, Department of Biology, Whittier College, Whittier, California 90608, USA; e-mail: sgoldberg@whittier.edu.

COLUBER CONSTRICTOR **(Racer). FORAGING BEHAVIOR.** Foraging strategies of snakes have been linked to their morphology, physiology, and ecology (Mushinsky 1987. *In* Seigel et al. [eds], Snakes: Ecology and Evolution Biology, pp.302–334, McGraw-Hill, New York). Snakes considered ambush predators balance low energy expenditure with low food intake, while active foragers have greater energy expenditure, but high food intake (Secor and Nagy 1994. Ecology 75:1600–1614). *Coluber constrictor* is considered an active generalist forager that routinely takes both endothermic and ectothermic prey (Klimstra 1959. Copeia 1959:210–214; Shewchuk and Austin 2002. Herpetol. J. 11:151–155). It has been suggested the fundamental food niche of *C. constrictor* is that of an insect eater (primarily orthopteran), with vertebrate prey being taken opportunistically and more frequently in fragmented feeding grounds, which necessitate larger movements by the snake, and more chance encounters with vertebrate prey (Fleet 2009. Southwest. Nat. 8:31–40). Active foragers such as *C. constrictor* typically rely on sight to target and capture food (Mullin et al. 1998. Am. Midl. Nat. 140:397–401), and frequently prefer moving over non-moving prey (Herzog and Burghardt 1974. Herpetologica 30:285–289; Cooper et al. 2000. Amphibia-Reptilia 21:103–115).

In May of 2004 at Flat Rock Cedar Glade and Barrens, located east of Murfreesboro, Rutherford Co., Tennessee, USA, a radio-telemetered adult male *C. constrictor* (SVL = 87.3 cm) was observed three times within a 10 min period aerially attacking a swarm of small gnat-like insects. These observations took place on a partly cloudy, warm, afternoon (1215–1225 h) in an open cow pasture with grass approximately 30 cm high. This snake spent much of its time in the pasture and, as indicated by scat samples collected from *C. constrictor* observed in this mixed habitat area, foraged on the abundant orthopterans. The swarm of insects hovered directly above where the snake was observed and the behaviors all occurred within a 25 m^2 area. The *C. constrictor* raised the anterior portion of its body off of the ground in a typical foraging posture and, with its mouth open, made a series of short, controlled, lunges toward the swarm of insects. Since these observations were made from a distance (~15 m) using binoculars, it was unclear if the snake was successful in capturing any prey. Whether for food, or out of annoyance, the actions of the snake suggested that it was targeting the swarm.

To our knowledge this is the first report of *C. constrictor* making aerial attacks on small swarming insects. Although anecdotal, these observations support the idea that *C. constrictor* is an opportunistic, generalist forager and suggest that food items are selected based on availability, with foraging efficacy playing a lesser role in prey selection.

COLUBER (= MASTICOPHIS) FLAGELLUM PICEUS **(Red Racer). ARBOREAL/NOCTURNAL BEHAVIOR.** Many species of snakes display arboreal behavior and are often found in vegetation many meters above ground. Mojave Desert snake species rarely get very far above the ground surface and are perhaps limited by predominantly low growing vegetation. *Coluber flagellum piceus* is considered strictly diurnal and although may ascend vegetation while active, is thought to retreat to subterranean refugia at night. Werler and Dixon (2000. Texas Snakes: Identification, Distribution, and Natural History. University of Texas Press, Austin. 437 pp.) stated "The western coachwhip is active above ground only during daylight hours. It almost invariably retires to depths of an animal burrow before sundown, where it spends the night." The normal morning activity period for *C. flagellum* appears to be from approximately 0700–1000 h from June through September (Jones and Whitford 1989. Southwest. Nat. 34:460–467). Secor and Nagy (1994. Ecology 75:1600–1614), and Secor (1995. Herpetol. Monogr. 9:169–186) determined that the average body temperature for active above ground activity of *C. flagellum* was (33.1°C ± 0.1°C, range of 24.0°C–40.8°C, N = 502), stating that coachwhip snakes were seldom active on the surface with body temperatures below 28°C. Here, I report a *C. f. piceus* that apparently spent the night draped in a Creosote Bush (*Larrea tridentata*).

On 24 June 1995 I observed an unusual behavior exhibited by a half grown *C. f. piceus* (SVL ca. 650 mm) basking in a moderate-sized creosote bush approximately 1 m above the ground at 0610 h in Piute Valley, Clark Co., Nevada, USA. I approached the snake slowly taking numerous photographs while the snake remained motionless in the shrub (Fig. 1). When I was within arm's length of the snake I reached out and captured it by hand to find that it

FIG. 1. *Coluber flagellum piceus* moments after sunrise (0610 h) in a Creosote Bush, Clark Co., Nevada.

appeared as cold as the ambient air temperature at waist height, which was 20°C at the time. All indications are that the snake had spent the night above ground draped in the Creosote Bush where I first observed it that morning. Numerous other desert reptiles are known to be nocturnal although nocturnal activity for *C. flagellum* is not commonly observed. Therefore, I assert that this snake likely placed itself in this precarious position sometime near dusk or possibly even at night and spent the night as depicted in Fig. 1.

I thank R. Fisher, K. Nussear, J. Richmond, and S. Jones for suggestions on this manuscript, and K. Drake and K. Nolte for preparing the figure.

PHILIP A. MEDICA, U.S. Geological Survey, Western Ecological Research Center, 160 N. Stephanie Street, Henderson, Nevada 89024, USA; e-mail: pmedica@usgs.gov.

***DRYMOBIUS MARGARITIFERUS* (Speckled Racer). DEFENSIVE BEHAVIOR: THANATOSIS.** Thanatosis, also known as letisimulation or death feigning behavior, has been recorded in several families and species of snakes, but is most often associated with the genus *Heterodon* (Gehlbach 1970. Herpetologica 26:24–34). Although *Drymobius margaritiferus* is a common and widespread species throughout much of Middle America (Lee 1996. The Amphibians and Reptiles of the Yucatán Peninsula. Comstock Publ. Assoc., Ithaca, New York. 500 pp.), little is known about its ecology and behavior. To our knowledge, thanatosis has not been recorded in *D. margaritiferus*.

At 1112 h (CST) on 29 October 2003, a juvenile *D. margaritiferus* (total length ca. 50 cm) was found crossing State Highway 66 in the Sierra Tamalave in an area of tropical deciduous forest in the Municipality of Ocampo, Tamaulipas, Mexico (22.820833°N, 99.289167°W, datum: WGS84; elev. 389 m.; air temp. 28.3°C). It was detained for ca. 30 min to collect data and photographs. The animal, which appeared to be healthy and alert, was photographed on the side of a nearby dirt road. The snake was in perpetual motion in its effort to escape and it attempted to bite repeatedly while being photographed. After a period of approximately 15 min of struggling, it suddenly became very weak and appeared to have difficulty moving. The snake grew increasingly weak and after about 30–45 sec its body went completely limp and motionless except for the tail, which squirmed and twitched for the next two or three minutes. Unlike snakes of the genus *Heterodon*, this specimen did not exhibit gaping, extend its tongue, or attempt to right itself or to move itself from any given position. When held by the tail or at mid-body the snake dangled, completely limp, and when placed on the ground the snake remained limp and motionless in whatever position it was placed. Believing the snake was in fact dead, it was posed in a lifelike position and a few photographs were taken. After a minute or two, my attention (and eye contact) turned away from the snake and while changing film and putting lens away, the snake was observed on the ground nearby tongue flicking and raising its head. The snake was gently picked up and examined, and although it seemed slightly more subdued and ceased to bite, it appeared to be normal and soon resumed its efforts to escape. The snake was released near the point of capture where it quickly retreated and disappeared into dense foliage.

A second observation of this behavior was observed in the Municipality of Gonzalez, Tamaulipas, 29 km N of the town of Gonzalez (23.087222°N, 98.469444°W, datum: WGS84; elev. 360 m.; 28.3°C) on 20 September 2006, 1100 h. (CST). An adult *D. margaritiferus* (SVL = 83.8 cm) was collected in tropical deciduous forest in the southern foothills of the Sierra de Tamaulipas in a riparian area of the Arroyo el Cedral. As above, the specimen went limp and became motionless while being photographed. When the anterior half of the snake was raised off the ground the head and anterior body hung limp and when released the head of the snake came to rest upside down, with an elevated coil in the neck, and the posterior half of the body dorsal side up. When left in this position, the snake remained motionless. Unlike the first observation, this snake seemed to show slight signs of recovery as it was being photographed for ca. 5 min. A few times it started to orient its head right side up and made some feeble attempts to move its body forward, but it repeatedly relapsed. The second snake was also released at the location of its capture after being photographed.

Finally, 30 *D. margaritiferus*, 21 alive and 9 DOR, were recorded in field surveys of Tamaulipas conducted between 2003 and 2007. Seven of the live specimens were collected, handled, measured, photographed, and then released. Two of the seven (28.5%) individuals that were handled exhibited thanatosis. Photographs of the two specimens were deposited at University of Texas Arlington Digital Collection (UTADC 6808–6810). DOR specimens were salvaged and deposited at the Universidad Autónoma de Nuevo León.

Fieldwork was conducted under SEMARNAT permit no. 00800/06 and funded by HZI. We thank Toby J. Hibbitts and James R. Dixon for their assistance in the field in September of 2006.

***ERYTHROLAMPRUS BIZONA* (Black-Ringed False Coralsnake). ARBOREALITY.** *Erythrolamprus bizona* is a moderately common snake that ranges between Costa Rica and Colombia. All accounts suggest that the snake is terrestrial (Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna between Two Continents, between Two Seas. Univ. Chicago Press, Chicago, Illinois. 934 pp.; Solórzano 2004. Snakes of Costa Rica: Distribution, Taxonomy, and Natural History. Instituto Nacional de Biodiversidad, Santo Domingo de Heredia, Costa Rica. 791 pp.). On 6 January 2011, at 1005 h, at La MICA Biological Station in

El Copé, Coclé Province, Republic of Panamá (08.66°N, 80.61°W; WGS84) we observed an adult *E. bizona* two meters high in a small tree. The snake moved to the end of the branch and then dropped to the ground and crawled away. *Erythrolamprus bizona* have not previously been reported to be arboreal. This observation expands the habitats that may be used by this species.

RAY, La MICA Biological Station, El Copé de La Pintada, Coclé Province, Republic of Panama (e-mail: julie.ray@lamica.org); **DENISE KÜNG**, Ecology Group, Institution of Biology, Evolution and Environmental Studies, University of Zurich, Winterthurestrasse 190, CH-8057, Zúrich, Switzerland; **PABLO SANTANA**, La MICA Biological Station, El Copé de La Pintada, Coclé Province, Republic of Panama.

***EUNECTES BENIENSIS* (Beni Anaconda). DIET: CANNIBALISM.** Cannibalism has been reported four times in the genus *Eunectes* (O'Shea 1994. Herpetol. Rev. 25:14; Rivas and Owens 2000. Herpetol. Rev. 31:45–46; Barros et al. 2011. Herpetol. Rev. 42:290–291). Two of these records were considered sexual cannibalism (Rivas and Owens, *op. cit.*), where a large female consumed a male of the same species during the breeding season. In this contribution we present the first report of cannibalism in the recently discovered *Eunectes beniensis*.

On 24 January 2010, as part of a comprehensive study of the spatial ecology and life history of *E. beniensis* in the Beni River basin, Beni Department, Bolivia, we captured a female *E. beniensis* (total length = 220 cm; 6 kg without prey) in a rice field (14.8°S, 64.467°W; WGS84). Following capture, the female regurgitated a conspecific male (total length = 192 cm; 2.5 kg; sex determined by presence of exposed hemipenes). Although the cephalic region of the regurgitated specimen was partially decomposed, it was possible to recognize the color pattern typical of *E. beniensis*. Because prior records of cannibalism in *E. murinus* occurred during or directly following the mating season (dry season), Rivas and Owens (*op. cit.*) believed that they were examples of sexual cannibalism. However, this report of cannibalism in *E. beniensis* occurred in the middle of the rainy season and thus was not likely to be associated with reproductive activities. The presence of cannibalism in three species of *Eunectes* in different locations suggests that it may be a relatively common strategy in the group.

Funding for this project was provided by the Viceministerio de Medio Ambiente, Biodiversidad, Cambios Climáticos y Gestión y Desarrollo Forestal, and Fundación Amigos de la Naturaleza (FAN- Bolivia). We thank the Ibiato community for welcoming us in their village. Orlando Eirubi provided invaluable help during field work.

***HOLOGERRHUM PHILIPPINUM* (Philippine Stripe-lipped Snake). REPRODUCTION.** One of four snake genera endemic to the Philippines, the genus *Hologerrhum* contains only two species, known from fewer than 20 specimens worldwide (Brown et al. 2000. Asiatic Herpetol. Res. 9:1–13; Leviton 1963. Proc. California Acad. Sci. 31:369–416; Leviton 1965. Phil. J. Sci. 94:519–533). The apparent absence of adult males in collections previously led taxonomists to speculate that *H. philippinum* might be an all-female, parthenogenetic species (A. Leviton, pers. comm.). During recent fieldwork in the northern Philippines, we collected an adult male *H. philippinum* (total length = 302 mm; 4.8 g; Fig. 1). The specimen was observed on 28 December 2010, in mixed primary- and secondary-growth forest, under a rock in a dry river bed, in the Angat Dam Watershed Reserve, Sitio Langud, Barangay San Lorenzo, Municipality of Norzagaray, Bulacan Province, Luzon Island, Philippines (14.93231°N, 121.20562°E, WGS-84; elev. 194 m). This is the first known reproductively mature male specimen of *H. philippinum*; the only other male specimen is a juvenile with hemipenes retracted (USNM 498718; Brown et al., *op. cit.*). The specimen is deposited at the herpetological collections of the Biodiversity Institute, University of Kansas (RMB 13628).

***IMANTODES CENCHOA* (Brown Blunt-Nosed Vinesnake). MAXIMUM SIZE.** *Imantodes cenchoa* is a relatively abundant neotropical arboreal snake that ranges from southern Mexico to Argentina. It is recognized by its long slender body and extremely thin neck. Savage (2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna between Two Continents, between Two Seas. Univ. Chicago Press, Chicago, Illinois. 934 pp.) reported a maximum size of 1250 mm for female *I. cenchoa*. On 5 December 2006, at 2000 h, in Omar Torrijos National Park, Coclé Province, Republic of Panamá (08.66°N, 80.61°W, datum: WGS84), we found a female *I. cenchoa* that measured 1369 mm total length (SVL = 943 mm) and weighed 47.4 g. This snake was marked and released at the site of capture. On 8 March 2007, at 2236 h, in Omar Torrijos National Park we found a female *I. cenchoa* that measured 1439 mm total length (SVL = 986 mm) and weighed 36.0 g (without prey). This snake contained a *Dactyloa frenata* (19.1 g) and a large anole egg (1.3 g) prey items (Ray et al. 2011. Herpetol. Rev. 42:100). Photographs of this specimen were deposited at the Amphibian and Reptile Diversity Research Center, University of Texas at Arlington (UTADC 6526–27). The first record increased the maximum known total length of female *I. cenchoa* by 119 mm (8.6%) and the second by 189 mm (15.1%).

We thank J. A. Santana, Omar Torrijos National Park, the Smithsonian Tropical Research Institute, Autoridad Nacional del Ambiente (Permit SE/A-44-06), the National Science Foundation (IBN-0429223, IBN-0429223, IOB-0519458), and researchers of the TADS Project for field assistance, permits, and/or funding.

RAY, La MICA Biological Station, El Copé de La Pintada, Coclé Province, Republic of Panama (e-mail: julie.ray@lamica.org); **ANDREW HEIN,** Department of Zoology, 223 Bartram Hall, University of Florida, Gainesville, Florida 32611, USA; **AURELIO GONZALEZ,** Asociación de Guías Locales de Conservación Ambiental, El Copé, Coclé Province, Panamá; **SCOTT GOETZ,** Department of Biological Sciences, Old Dominion University, Norfolk, Virginia 23529, USA; **MELISSA MILLER,** Department of Biological Sciences, Sam Houston State University, Huntsville, Texas 77341, USA.

***LAMPROPELTIS GETULA* (Common Kingsnake). DIET AND FORAGING.** The ability of a snake to successfully forage is a product of its morphology, physiology, and ecology (Mushinsky 1987. *In* Seigel et al. [eds], Snakes: Ecology and Evolution Biology, pp. 302–334, McGraw-Hill, New York). Consuming non-prey items by mistake could be detrimental to the snake and result in death. Thus, selection should favor behaviors that maximize a snake's ability to accurately discriminate between prey and non-prey items (Cooper et al. 1990. Chemoecology 1:86–91; Reiserer 2002. *In* Schuett et al. [eds], Biology of the Vipers, pp. 361–384, Eagle Mountain Publishing, Eagle Mountain, Utah).

Lampropeltis getula is an active forager that relies on both sight and chemoreception to locate and capture prey (Jackson et al. 2004. Zoology 107:191–200; Williams and Brisbin 1978. Herpetologica 34:79–83). This species, like others in the genus *Lampropeltis*, is known to routinely consume ectothermic (e.g., squamates) and endothermic (e.g., birds and mammals) prey, as well as squamate eggs (Clark 2009. Southwest. Nat. 54:352–353). Studies have investigated prey selection in snakes, including *Lampropelis* (Fitch 1978. Trans. Kansas Acad. Sci. 81:353; Greene and Rodriguez-Robles 2003. Copeia 2003:308–314), however, little is known about their ability to discriminate between certain qualitative traits of prey (e.g., color and texture).

In June of 2003 at Flat Rock Cedar Glade and Barrens, located east of Murfreesboro, Rutherford Co., Tennessee, USA, a *Coluber constrictor* nest was predated upon by an adult male *L. getula* (SVL = 71.6 cm). The snake consumed three *C. constrictor* eggs and an artificial egg, which had been constructed to record nest temperature, leaving behind two other *C. constrictor* eggs. Despite being of similar size, shape, and weight, the artificial egg was bright yellow in color (i.e., coated in Plasti Dip®), denser, and had a smoother texture than a *C. constrictor* egg. The oviposition site and artificial egg, which had only been there for approximately two weeks, were located in an ecotone between a cedar forest and a glade. The *L. getula* was located approximately 25 m away under a large rock, and the food items were palpated in order to retrieve the artificial egg. The snake was promptly release unharmed at the site of capture after recovering the artificial egg and recording basic measurements.

This observation indicates that *L. getua* will mistakenly consume non-prey items in the wild despite its visual and chemosensory capabilities. Similar observations have been made in other snakes (Ernst and Ernst 2003. Snakes of the United States and Canada, Smithsonian Institution Press, Washington, DC. 680 pp.; Souza et al. 2004. J. Herpetol. Med. Surg. 14:4–5) suggesting that despite some discriminatory abilities in prey selection, snakes may become confused when non-prey items that resemble prey are encountered while foraging. To our knowledge this is the first report of this type of behavior in *L. getula*.

J. JEFFREY GREEN, Division of Math and Natural Sciences, Nashville State Community College, 120 White Bridge Road, Nashville, Tennessee 37209, USA (e-mail: jeff.green@nscc.edu); **VINCENT A. COBB**, Department of Biology, Middle Tennessee State University, 1301 East Main Street, Murfreesboro, Tennessee 37132, USA (e-mail: vcobb@mtsu.edu).

***LAMPROPELTIS GETULA HOLBROOKI* (Speckled Kingsnake). DIET.** *Lampropeltis getula holbrooki* is known to prey on reptiles and reptile eggs, amphibians, mammals, and several species of birds that construct open-cup nests (Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Inst. Press, Washington DC. 680 pp.). One published account documents *L. g. holbrooki* depredating nestlings in open-cups: the Dickcissel (*Spiza americana*) and the Red-winged Blackbird (*Agelaius phoeniceus*; Facemire and Fretwell 1980. Wilson Bull. 92:249–250). These nests were located 15 cm and 70 cm above the ground, respectively. *Lampropeltis g. holbrooki* has also been documented to depredate nestling Indigo Buntings (*Passerina cyanea*) and Field Sparrows (*Spizella pusilla*), both species that construct open-cup nests within 1 m of the ground (Stake et al. 2005. J. Herpetol. 19:215–222). Although *L. g. holbrooki* has been observed depredating Eastern Bluebird (*Sialia sialis*) nest-boxes in Texas (Keith Kridler, pers. comm.), there is no published documentation of *L. g. holbrooki* climbing an artificial structure and consuming this species of cavity-nesting bird.

On 25 June 2010, at 1130 h, we discovered a *L. g. holbrooki* inside of a constructed Eastern Bluebird nest-box mounted 1.5 m above the ground. This nest box was mounted on a fence at the edge of a hay field off of state highway 51 in Payne Co., Oklahoma, USA (36.1152°N, 97.3007°W; datum WGS84). There were four 7-day-old bluebird nestlings inside the box being tended by both parents. The snake could only enter through the entry hole (3.81 cm in diameter). The snake was observed eating one nestling and constricting another. The observer opened a hinged door that was held shut with a nail and took photos, then closed the door without disturbing the snake. Only one nestling was consumed at this time and the rest remained alive. We monitored the box for the next two days and observed one nestling missing on each successive visit. Although we did not observe any other depredation events during our visits, we speculate these nestlings were preyed upon by the same snake. Similar return behavior to a nest was documented by Stake et al. (2005. J. Herpetol. 19:215–222). Only one nestling fledged from this box on 7 July 2010. To the best of our knowledge, this is the first documentation of *L. g. holbrooki* climbing and consuming nestlings inside of a secondary cavity.

We thank Matt Anderson for his assistance and Keith Kridler for sharing unpublished data.

JENNIFER L. BURTKA (e-mail: jay.burtka@okstate.edu), **ALEX W. FORD**, and **JENNIFER L. GRINDSTAFF**, Department of Zoology, 501 Life Sciences West, Oklahoma State University, Stillwater, Oklahoma 74078, USA.

***LAMPROPELTIS ZONATA* (California Mountain Kingsnake). DIET.** *Lamproteltis zonata* is distributed from southern Washington state to northern Baja California and throughout the mountain ranges of California (Stebbins 2003. Peterson Field Guide: Western Reptiles and Amphibians, 3rd ed. Houghton Mifflin Co., New York. 366 pp.). The diet of this species has been examined in detail (Greene et al. 2003. Copeia 2003:308–314); it appears that the bulk of its diet consists of squamate reptiles

FIG. 1. *Lampropeltis zonata* constricting and beginning to consume a bat (*Myotis* sp.) headfirst.

and their eggs, but larger individuals may occasionally consume mammals and birds.

At 1350 h, on 20 October 2009, one of us (CW) observed a *L. zonata* constricting a bat of the genus *Myotis* along the Rogue River trail of southwestern Oregon just off BLM Rd. 34-8-1 (42.663661°N, 123.611255°W; datum WGS84) (Fig. 1). This section of the trail is adjacent to a talus slide. It is likely that the kingsnake found and captured the bat within the talus, and the two subsequently fell and rolled onto the trail. The two were not disturbed and actual consumption of the bat was not observed. This is the first record of *L. zonata* attempting predation upon a bat.

EDWARD A. MYERS, Department of Biology, The Graduate School and University Center, The City University of New York, 365 Fifth Avenue, New York, New York 10016, USA (e-mail: emyers@gc.cuny.edu); **CINDY WEDEKIND** (e-mail: cindy_wedekind@blm.gov) and **JASON REILLY**, Grants Pass Interagency Office, 2164 NE Spalding Avenue, Grants Pass, Oregon 97526, USA (e-mail: jason_reilly@blm.gov).

***LEPTODEIRA PUNCTATA* (Western Cat-Eyed Snake). DIET.** Snakes in the genus *Letpodeira* prey primarily upon anurans and small lizards (Duellman 1958. Bull. Amer. Mus. Nat. Hist. 114:1–152), along with other reptiles and amphibians (Burchfield 1993. Bull. Chicago Herpetol. Soc. 28:266–267). Although species from the family Hylidae have been documented (Hardy and McDiarmid 1969. Univ. Kansas Publ. Mus. Nat. Hist. 18:39–252), *Smilisca fodiens* (=*Pternohyla fodiens*; Northern Casque-Headed Frog) has not been reported as prey of *Leptodeira punctata* (Duellman and Trueb 1966. Univ. Kansas Publ. Mus. Nat. Hist. 17:281–375). On 5 August 2008, at approximately 1930 h, we encountered an adult *L. punctata* with an adult *S. fodiens* in its grasp near the town of Concordia, Sinaloa, Mexico (23.2725°N, 106.03585°W; datum WGS84) (Fig. 1). The *S. fodiens* was inflated with air in an attempt to prevent the snake from consuming it. The *L. punctata* continuously chewed on the *S. fodiens* for approximately 45 min until the frog deflated and was consumed. This is the first documentation of a *L. punctata* preying upon a *S. fodiens*.

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

FIG. 1. *Leptodeira punctata* preying upon an adult *Smilisca fodiens* in Sinaloa, Mexico.

We thank the many people of Mexico who assisted us in the field, and the Mexican government for permitting access to their country, its wonderful herpetofauna, and ecological diversity. All research and collecting were done under the authority of SEMARNAT scientific research permit SGPA/DGVS/03804, issued to IR.

Box 120551, San Diego, California 92112, USA.

***LIOPHIS DILEPIS* (Lema's Ground Snake) and *PHILODRYAS OLFERSII LATIROSTRIS* (Lichtenstein's Green Racer). BROMELIAD REFUGIA.** *Liophis dilepis* is colubrid species with a disjunct distribution, including Caatinga and Cerrado areas in northeastern and southern Brazil, and Chaco areas of Paraguay, northern Argentina, and southern Bolivia (Giraudo 2001. Serpientes de la Selva Paranaense y del Chaco Húmedo. L.O.L.A., Buenos Aires, Argentina. 328 pp.). In Argentina and southern Paraguay, the species inhabits savannas, xerophilous and semi-xerophilous forests in the Chaco biogeographic province (Giraudo, *op cit.*). *Philodryas olfersii* is a colubrid snake that is widely distributed in tropical and subtropical areas of cis-Andean South America from Guiana, Venezuela, and Colombia, to subtropical areas of Argentina and Uruguay (Thomas 1976. A Revision of the South American Colubrid Snake Genus *Philodryas* Wagler, 1983. Ph.D. dissertation, Texas A&M University, College Station. 338 pp.). In Argentina, *P. o. latirostris* is found in the humid Chaco phytogeographical region and other mesophytic vegetation and gallery forests along the Paraná River (Thomas, *op cit.*; Giraudo, *op cit.*).

We conducted periodic diurnal surveys to investigate the fauna associated with colonies of *Aechmea distichantha* (Bromeliaceae) at El Perichón, 10 km NE of Corrientes City, Argentina (27.4321111°S, 58.7466111°W, datum: WGS84). The area is included within the Chacoan Domain, Oriental Chaco District (Carnevali 1994. Fitogeografía de la Provincia de Corrientes. Gobierno de la provincia de Corrientes e INTA. 324 pp.), and is characterized by the presence of numerous temporary, semipermanent, and permanent water bodies. The original plant community at the study site was *Schinopsis balansae* "quebracho" forest, which is currently extremely degraded and largely replaced by sclerophyllous forest with prevalence of *Prosopis affinis*, *P. nigra*, *Acacia caven*, *Celtis* spp., and numerous colonies of *Aechmea distichantha* and *Bromelia* spp. (Carnevali, *op. cit.*). On 1 October 2007, at 1726 h, we found an adult *L. dilepis* inside

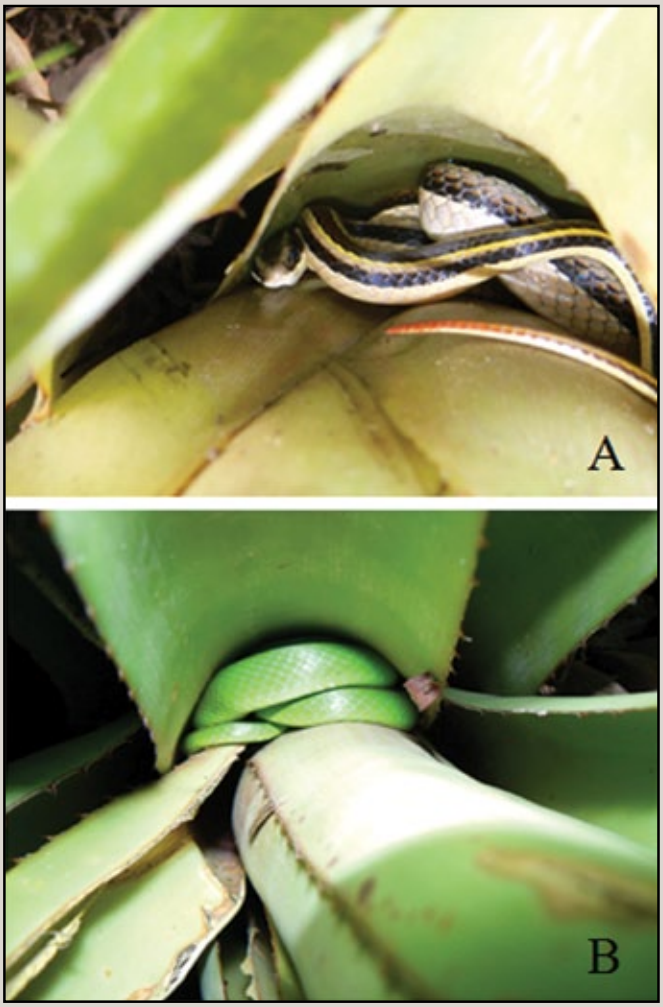

FIG. 1. A) *Liophis dilepis* and B) *Philodryas olfersii latirostris* hidden inside the axils of *Aechmea distichantha*.

an *A. distichantha* leaf axilla (Fig. 1A). Six days before, on 27 September 2007, at 1900 h, within another *A. disctichantha* colony, we discovered an adult *P. o. latirostris* hidden inside a bromeliad axil (Fig 1B). Considering that these snakes were found hidden in evening hours, it is possible that they use the axils of *Aechmea distichantha* as nocturnal shelter. It is also important to note that bromeliad axils have the capacity to store water for long periods and are used by several amphibian species. Thus, these plants may provide snakes abundant food in addition to shelter.

EDUARDO F. SCHAEFER (e-mail: eclschaefer247@yahoo.com.ar) and **MARTA I. DURÉ** (e-mail: martadure@yahoo.com), Centro de Ecología Aplicada del Litoral (CECOAL – CONICET), Ruta 5, km 2.5, 3400, Corrientes, Corrientes, Argentina.

***LIOPHIS EPINEPHELUS* (Night Ground Snake). DIET.** *Liophis epinephelus* is found in South America from Venezuela to Peru, at or above 2200 m in Ecuador and Peru (Dixon 1989. Smithson. Herpetol. Info. Serv. No. 79). *Liophis* are thought to feed primarily on anurans, but their diet is also known to include invertebrates, lizards, fishes, birds, small rodents (Esqueda et al. 2009. Acta Herpetol. 4:171–175), and squamates (Michaud and Dixon 1989. Herpetol. Rev. 20:39–41), including only a few records from the family Geckkonidae. In this note I report the first record of a *Liophis* feeding on gecko of the genus *Lepidobleparis*.

On 7 August 2010, a *Liophis epinephelus* (SVL = 140 mm) was captured in a disturbed-regenerating portion of Reserva Las Gralarias, a private 1064-acre reserve located in northwestern Ecuador, Pinchincha (elev. 1750–2350 m). Almost immediately upon being handled the snake regurgitated a *Lepidobleparis conolepis* (SVL = 38.5 mm). The gecko showed little evidence of digestion, indicating this was a very recent meal. The *L. conolepis* specimen was collected and deposited in the herpetological collection of Museo de Zoologia QCAZ, Pontifica Universidad Catolica del Ecuador and identification was verified by Omar Torres Carvajal.

TIM KRYNAK, Cleveland Metroparks, 3037 SOM Center Rd. Willoughby Hills, Ohio 44094, USA; e-mail: tkrynack@aol.com.

***MICRURUS MIPARTITUS* (Redtail Coralsnake). DIET.** New World coralsnakes are predators of elongate vertebrates, especially snakes, lizards, and amphisbaenians (Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna between Two Continents, between Two Seas. Univ. Chicago Press, Chicago, Illinois. 934 pp.). They apparently do not eat amphibians very frequently (Wells 2007. The Ecology and Behavior of Amphibians. Univ. Chicago Press, Chicago, Illinois. 1148 pp.), although some species prey upon caecilians (Roze 1996. Coral Snakes of the Americas: Biology, Identification, and Venoms. Krieger Publ., Malabar, Florida. 328 pp.). Here we report *Micrurus miparitus* preying upon a caecilian, *Caecilia thompsoni*.

On 25 May 2010, at 1240 h, we observed a *M. mipartitus* (total length = 46.5 mm) struggling with a *C. thompsoni* (total length = 47.3 mm) for about 25 min at ICA (Instituto Colombiano Agropecuario) station in Tolima, Colombia (4.4388889°N, 75.2319444°W, datum WGS84; elev. 1150 m). We observed the coralsnake pursuing and biting the caecilian, primarily on the neck (Fig. 1A). Once the caecilian was immobile, it was ingested head-first (Fig. 1B). However, the caecilian, which was longer than the coralsnake, could not be totally consumed and was eventually regurgitated.

MANUEL HERNANDO BERNAL, Grupo de Herpetología, Eco-Fisiología & Etología, Universidad del Tolima, Colombia (e-mail: mhbernal@ut.edu.co); **GLORIA MILENA PALMA**, Instituto Colombiano Agropecuario ICA, Tolima, Colombia (e-mail: gloria.palma@ica.gov.co).

FIG. 1. *Micrurus mipartitus* biting (A) and ingesting (B) a caecilian, *Caecilia thompsoni*.

***OPISTHOTROPIS KUATUNENSIS* (Striped Stream Snake). DIET.** *Opisthotropis kuatunensis* is a non-venomous aquatic snake with an average total length of 35–48 cm (Karsen et al. 1998. Hong Kong Amphibians and Reptiles. Provisional Urban Council, Hong Kong. 186 pp.). This snake is endemic to southern China and inhabits rocky hill streams in forests. It has been reported to feed on tadpoles and fishes in captivity (Karsen et al., *op. cit.*). Information concerning the diet of this species, or any other species of *Opisthotropis* in the wild, is very limited. *Opisthotropis lateralis* has been reported to feed on crabs in its natural environment (Karsen et al., *op. cit.*). Here I report the first documented observation of *O. kuatunensis* feeding on a crab in the wild.

At 2120 h on 3 October 2010, on Tai Mo Shan (22.40847°N, 114.12895°E, datum WGS84; elev. 769 m), New Territories, Hong Kong, while conducting an amphibian survey, I observed an *O. kuatunensis* (SVL = 52.5 cm; total length = 64.0 cm; sex unknown) swimming in the stream with a dead freshwater crab, *Cryptopotamon anacoluthon*, in its mouth. Upon capture, the snake released the carcass of the crab, which was collected and preserved in ethanol. The crab was presumably freshly molted, since its carapace was soft and deformed by bites from the snake. Except for two left legs, all chelae and other legs were missing from the carcass and may have been consumed by the snake (Fig. 1). This observation of a crab being eaten by *O. kuatunensis* is surprising because this species' small blunt teeth and relatively small gape size suggest that it preys on small or soft-bodied animals. In this observation, the dimensions of the crab's carapace were 2.0 cm (width) by 1.5 cm (length) while the head width and body width of the snake was approximately 1 cm. Despite its small gape size, the snake probably could have eaten the crab because it was freshly molted. It is unlikely that *O. kuatunensis* would be able to swallow the crab intact if it was hard-shelled.

FIG. 1. *Opisthotropis kuatunensis* (above) found feeding on a freshwater crab (*Cryptopotamon anacoluthon*; above and below) on Tai Mo Shan, Hong Kong.

It is possible that the snake may have been scavenging on a dead crab. Aquatic snakes may scavenge more frequently than other snakes since they tend to rely on chemical cues for prey detection underwater (DeVault and Krochmal 2002. Herpetologica 58:429–436). Although I did not observe the initial encounter of the *O. kuatunensis* with the crab, the relatively intact carapace of the dead crab suggested that the crab was not likely remains left by another predator. Potential crab predators in the area include Big-headed Turtles (*Platysternon megacephalum*) and Giant Spiny Frogs (*Paa spinosa*), both of which would have inflicted obvious damage to the crab or consumed the crab whole.

The aquatic snake *Gerarda prevostiana* preys on crabs much larger than its head (Jayne et al. 2002. Nature 418:143). This species circumvents the constraint of its gape limit by selectively preying on freshly molted crabs; it tears off and consumes the crab's legs first by a "loop-and-pull" action and then discards body parts that are too large to swallow (Jayne et al., *op. cit.*). The carcass of the freshly molted crab with missing legs suggests that *O. kuatunensis* may represent another species that engages in this unusual crab-eating behavior. Additionally, *O. kuatunensis* may selectively prey on or scavenge freshly molted crabs that are more easily ingested. Becasue crab molting can be temperature-triggered and thus highly seasonal (Yamaguchi and Takamatsu 1980. Kumamoto J. Sci. Biol. 15:1–27), crabs may be a seasonally important food source for *O. kuatunensis*.

I thank Kevin Wu for helping in field work, and Nancy Karraker and Kingsley Wong for valuable comments on the manuscript.

HON-KI CHAN, School of Biological Sciences, The University of Hong Kong; e-mail: honkichan@gmail.com.

***PITUOPHIS CATENIFER* (Gophersnake). DIET.** *Pituophis catenifer* feeds primarily on mammals, birds, lizards, eggs, and occasionally invertebrates (Diller and Johnson 1988. Herpetologica 44:228–233; Rodriquez-Robles 1998. Copeia 1998:463–466.; Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Institution Press, Washington D.C. 668 pp.). On 20 May 2009, we collected an adult male *P. catenifer* (total length = 99 cm) from a south-facing limestone outcrop directly below a large, shallow cave in Snake Creek Canyon, Great Basin National Park, Nevada, USA (38.9169°N, 114.1731°W; datum NAD83). Upon palpation, the snake regurgitated two male *Tamius dorsalis* (Cliff Chipmunk) pups (BYU 5660; verified by Jack Sites and Eric Rickart). To the best of our knowledge, this is the first record of predation on *T. dorsalis* by *P. catenifer*.

MARGARET HORNER (e-mail: margaret_horner@nps.gov) and **BRYAN HAMILTON** (e-mail: bryan_hamilton@nps.gov), National Park Service, Great Basin National Park, Baker, Nevada 89311, USA.

***PITUOPHIS CATENIFER DESERTICOLA* (Great Basin Gophersnake). PREDATION.** A variety of taxa have been observed to prey upon *Pituophis catenifer*, including mammals, birds-of-prey, and other snakes (Ernst and Ernst 2003. Snakes of the Unied States and Canada. Smithsonian Institution Press, Washington, D.C. 668 pp.). Here, we describe an unusual two-day observation of predation on a mature Great Basin Gophersnake by a Brown Trout (*Salmo trutta*).

The observation took place in Jones Canyon, Utah, USA, on the grounds of the Jones Hole National Fish Hatchery (JHNFH). Jones Creek emanates from springs at the head of Jones Canyon on hatchery grounds, and flows north to south 6.4 km to the Green River, approximately paralleling the Utah-Colorado border. The stream runs for ca. 0.3 km through a concrete channel across hatchery property before exiting into Dinosaur National Monument. The stream forms a pool at the end of the channel, which is cordoned off from public access by a 2 m high chain link fence. All insects and small wildlife species that fall into the channel are swept into this pool. The hatchery provides a plentiful supply of trout for the stream (primarily *S. trutta, Oncorhynchus mykiss,* and *O. clarki*) through escapes and planned releases. Numerous trout, many large, congregate in this pool, where they are protected from angling and are clearly visible. We have frequently observed snakes of various species basking atop the concrete walls of the channel. Through being startled or other accident, they may drop into the channel and are swept downstream to the pool. Partial bodies of snakes were observed on the bottom of the pool.

On 2 May 2006 the posterior portion of an adult *P. c. deserticola* was observed streaming from the mouth of a large (total length ca. 60 cm) *S. trutta,* the largest trout observed in the pool at the time. The visible length of the snake was approximately the same length as the fish carrying it and the diameter of the snake at the fish's mouth was ca. 2.5 cm. We estimate that the total length of the snake was ca. 90 cm. On the following day, the fish carrying the snake remained clearly visible throughout the day, with no readily apparent changes from the previous day. However, on 4 May 2006 there was no fish carrying a snake in the pool. We do not know if the snake was disgorged, swallowed, or if the fish vacated the pool. No whole or partial remnants of the snake were visible in the pool, only the portions of smaller snakes that were in the pool when observations began. To our knowledge, this is the first account of a Brown Trout consuming a mature *P. catenifer deserticola.*

STEVEN J. WAMBACK, USDA/Wildlife Services, 2820 East University Ave., Gainesville, Florida 32641, USA; **RICHARD M. ENGEMAN**, National Wildlife Research Center, 4101 LaPorte Ave., Fort Collins, Colorado 80521-2154, USA (e-mail: richard.m.engeman@aphis.usda.gov).

***PSEUDOBOA NIGRA* (Mussurana). DIET.** Two color morphs of *Pseudoboa nigra* exist in Brazil. The most common is plain black; the other is black with irregular white patches and might represent a different species (Orofino et al. 2010. Phyllomedusa 9:53–61). Although the diet of *P. nigra* consists primarily of lizards (Vanzolini et al. 1980. Répteis das Caatingas. Academia Brasileira de Ciências, Rio de Janeiro. 161 pp.), only two wild feeding events, both involving the black morph, have been reported (Avila and Ferreira 2006. Herpetol. Rev. 37:82; Rocha et al. 1999. Herpetol. Rev. 30:229). Here we report the first wild feeding observation of the black and white morph of *P. nigra* from Reserva Natural Vale, municipality of Linhares, Espírito Santo State, southeastern Brazil (19.1519444°S, 40.0708333°W; elev. 34 m). At ca. 0800 h, on 5 February 2008, we encountered an adult *P. nigra* (total length ca. 120 cm) in the process of swallowing a *Tropidurus torquatus* (total length ca. 25 cm; Fig. 1). At the time, the lizard was apparently dead and there were blood spots on posterior leg and feet. Despite our approach, the snake continued ingesting the lizard headfirst until it was consumed, approximately 1 h later.

We thank Francisco L. Franco (IBSP) for snake identification and Marco Aurélio de Sena and Miguel T.U. Rodrigues (IBUSP) for lizard identification.

FIG. 1. *Pseudoboa nigra* preying on *Tropidurus torquatus* (Linhares, Espírito Santo, Brazil).

ALICE CRISTINA MONDIN (e-mail: alice.mondin@yahoo.com.br), **ANA CAROLINA SRBEK-ARAÚJO**, Reserva Natural Vale, Linhares, ES. Gerência de Pesquisa & Desenvolvimento, Instituto Ambiental Vale, Rodov. BR 101, s/n, Km 122, CEP 29900-970, Linhares, ES, Brazil (e-mail: ana.carolina.srbek@vale.com); **MARCELO RIBEIRO DUARTE**, Laboratório de Herpetologia, Instituto Butantan, Av. Vital Brasil, 1500, CEP 05503-900, São Paulo, SP, Brazil (e-mail: mrduarte@butantan.gov.br).

***SISTRURUS MILIARIUS BARBOURI* (Dusky Pygmy Rattlesnake). PREDATION.** Known predators of *Sistrurus miliarius* include carnivorous mammals, hawks (*Buteo* spp.), and snakes (Ernst and Ernst 2002. Snakes of the United States and Canada. Smithsonian Institution Press, Washington D.C. 661 pp.). At 1852 h, on 13 November 2010, we observed a juvenile Yellow-crowned Night-Heron (*Nyctanassa violacea*) in the grass beside the road in Everglades National Park, Florida, USA

FIG. 1. Juvenile Yellow-crowned Night-Heron (*Nyctanassa violacea*) preying upon a *Sistrurus miliarius* in Everglades National Park, Florida.

(25.139098°N, 80.932128°W; datum WGS84). On closer inspection we ascertained the presence of an adult *S. miliarius* in the bird's beak (Fig. 1). We witnessed the heron thrash the snake approximately eight times in a 15-min span, with numerous tosses by the bird to adjust its grip on the snake, positioning its beak towards the head with each toss. The snake made several attempts to wriggle free but was apparently injured by the time we arrived and we assume the struggle commenced some time before our arrival. We watched until 1907 h when the heron ingested the entire *S. miliarius* and then flew off. The fact that we could see resistance from the snake as it writhed and tried to escape and the lack of any visible external injuries on the snake led us to believe the interaction was an act of predation and not scavenging of a road-killed animal by the *N. violacea*. Although wading birds are known to consume aquatic snakes (e.g., *Nerodia* spp.; Ernst and Ernst, *op. cit.*), to our knowledge, predation by wading birds on snakes of the genus *Sistrurus* has not been previously reported.

CHRISTOPHER R. GILLETTE, Department of Environmental Studies, Florida International University, Miami, Florida 33199, USA (e-mail: cgill002@fiu.edu); **LLOYD HEILBRUM,** Stetson University, Deland, Florida 32723, USA (e-mail: lheilb8013@aol.com).

***TANTILLA MELANOCEPHALA* (Black-headed Snake). DIET.** Little natural history data are available for the large genus *Tantilla*, with the exception of the North American *Tantilla gracilis* and *T. coronata* (e.g., Cobb 2004. Copeia 2004:397–402; Todd et al. 2008. Copeia 2008:388–394). The available information on the diet of the widespread *T. melanocephala* all pertains to southeastern Brazil and suggests an exclusively invertebrate diet consisting primarily of scolopendrid centipedes (Marques and Puorto 1998. Amphibia-Reptilia 19:311–318).

At 1430 h on 31 July 2010 an adult female *T. melanocephala* was found in a dry hole inside a steep-sided verge off a path in the Santa Lucía Cloud Forest Reserve, Pichincha, Ecuador (00.12917°N, 076.8048°W, datum WGS84; elev. ca. 1800 m). The specimen, which was in ecdysis, was found along with a number of eggs of the lizard *Riama oculata*. Upon capture one of the eggs was accidentally broken and the *T. melanocephala* subsequently started to 'lap up' the contents. It was unclear whether the specimen was intentionally in the area to feed upon the eggs. On closer examination, some of the eggs had hatched and others were complete but with two small holes in them, with no contents inside.

We thank Earthwatch Institute for funding our fieldwork, and all of the staff at the Santa Lucía Cloud Forest Reserve and Earthwatch volunteers for their support and help. We also thank Ernesto Villacis Perez for hatching out the eggs and Vanessa Aguirre P for identification of the *Riama oculata*.

SIMON T. MADDOCK, School of Biological Sciences, Bangor University, Bangor LL57 2UW, UK (e-mail: natureboyuk6@btinternet.com); **ELIZABETH F. SMITH** (e-mail: liz_smith1234@hotmail.co.uk), **MIKA R. PECK** (e-mail: m.r.peck@Sussex.ac.uk), School of Life Sciences, University of Sussex, Falmer, Brighton, Sussex, BN1 9QG, UK; **JORGE N. MORALES** Cooperativa de Conservación y Desarrollo Comunitario Sustentable Santa Lucía, Barrio La Delicia, Calle Kennedy s/n, Quito, Ecuador.

***THAMNODYNASTES HYPOCONIA*. DIET.** Snakes of the genus *Thamnodynastes* are widely distributed in South America, but little information is available on their biology (Franco and Ferreira 2002. Phyllomedusa 1:57–74). *Thamnodynastes hypoconia* is a small (mean SVL = 300 mm), semiarboreal, nocturnal species that inhabits riparian areas, the borders of gallery forests, marshes, and temporary ponds (Sawaya et al. 2008. Biota Neotrop. 8:127–149).

On 12 January 2010, at 2114 h, in an area of Cerrado in the municipality of Borebi, São Paulo State, Brazil (22.8035°S 49.0044°W, datum WGS84; elev. 652 m) we encountered an adult *T. hypoconia* (SVL = 350 mm) near a pond. The animal was next to the fence of a pitfall trap. The snake was collected and placed in a plastic bag. After about 30 min we observed that the snake had regurgitated a frog, which we subsequently identified as *Chiasmocleis albopunctata* (SVL = 37 mm), a microhylid that occurs in open areas in the central region of South America (Caramaschi and Cruz 1997. Herpetologica 53:259–268). The animals were collected and deposited in the Scientific Collection Jorge Jim, located at Departamento de Zoologia, Instituto de Biociências, UNESP, Campus de Botucatu, São Paulo State, Brazil (CCJJ 7932, License IBAMA/ICMBio - SISBIO 16778-1). On the same night, about 40 calling male *C. albopunctata* were recorded. *Thamnodynastes hypoconia* seems to specialize on anurans; Sawaya et al. (2008, *op. cit.*) reported one of these snakes trying to eat an adult *Elachistocleis ovalis*. This is the first record of *T. hypoconia* preying upon *C. albopunctata*.

We thank Duratex S.A. and FUNDIBIO for research support and William E. Duellman for the English revision.

FÁBIO MAFFEI (e-mail: maffei@ibb.unesp.br), **DANIEL CONTIERI ROLIM**, and **JORGE JIM**, Laboratório de Herpetologia, Departamento de Zoologia, Instituto de Biociências, Universidade Estadual Paulista, Botucatu, CEP 18618-000, São Paulo, Brazil.

***THAMNOPHIS BRACHYSTOMA* (Short-headed Gartersnake). REPRODUCTION: MAXIMUM LITTER SIZE.** Maximum litter size for *Thamnophis brachystoma* has been reported as 14 (Hulse et al. 2001. Amphibians and Reptiles in Pennsylvania and the Northeast. Cornell Univ. Press, Ithaca, New York. xii + 419 pp.; Swanson 1952. Am. Midl. Nat. 47:161–182). Here I report two litters exceeding this number. On 22 July 2005, I found a gravid female *T. brachystoma* at a site 6 km SE of Wattsburg, Erie Co., Pennsylvania, USA, that I maintained in captivity until parturition. She produced 16 young on 8 August 2005, of which 15 were live and one was stillborn. The mean mass of these 16 offspring (mean ± SD, [range]) was 0.95 ± 0.069 g (0.85–1.07 g). An additional stillborn individual (not measured) was produced on 10 or 11 August, for a total litter size of 17. Mass of the adult female on 6 August was 46.05 g, and was 23.10 g on 8 August, after parturition. The female and her living young were released at the point of capture. On 22 July 2007, I captured another gravid female (SVL = 396.8 mm, total length = 511.3 mm) at the same site. This individual gave birth to 16 live young in captivity on 2 August. Mean SVL (mean ± SD [range]) was 112.6 ± 2.13 mm (109.0–116.8 mm), and mean total length (mean ± SD, [range]) was 146.3 ± 4.25 mm (139.6–152.8 mm). There were 7 females and 9 males. The female (TREC R- 00028) and her litter (TREC R- 00029) were deposited in the collection of the Natural History Museum at the Tom Ridge Environmental Center.

MARK LETHABY, Natural History Museum at the Tom Ridge Environmental Center, 301 Peninsula Dr., Erie, Pennsylvania 16505, USA; e-mail: mlethaby@verizon.net.

***THAMNOPHIS ELEGANS* (Terrestrial Gartersnake). PREDATION.** At approximately 0715 h on 25 November 2009, 16 km N of Cabin City, Sanders Co., Montana, USA (47.474°N, 115.236°W, NAD83; elev. 1573 m) we observed a minimally digested *Tham-*

nophis elegans in the scat of a Gray Wolf (*Canis lupis*). The scat was fresh as it was still warm on top of melting snow at an air temperature of approximately -8°C. Snow depth was approximately 25 cm. We found tracks from at least five wolves in the area. The snake was intact and after cleaning it in the snow was clearly identifiable to species based on coloration. It is unknown whether the wolf found the snake active or removed the snake from its hibernaculum. In Montana, *T. elegans* are found at elevations up to 2499 m (Maxell et al. 2003. Herpetology in Montana. Northwest Fauna 5. Society for Northwestern Vertebrate Biology, Olympia, Washington. 135 pp.). Small animals including reptiles make up only a minor portion of a wolf's diet (Mech and Boitani 2003. Wolves: Behavior, Ecology and Conservation. University of Chicago Press, Chicago, Illinois, 428 pp.). However, this snake was not digested despite the gray wolf's efficient digestive tract (Mech and Boitani, *op. cit.*).

JANENE S. LICHTENBERG, Confederated Salish and Kootenai Tribes, Wildlife Management Program, P.O. Box 278, Pablo, Montana 59855, USA (e-mail: janenel@cskt.org); **DENNIS A. LICHTENBERG**, IAP, 33268 Terrace Lake Rd, Ronan, Montana 59860, USA.

***THAMNOPHIS SAURITUS SEPTENTRIONALIS* (Northern Ribbonsnake). REPRODUCTION: LITTER SIZE.** Litter size in *Thamnophis sauritus* is known to vary geographically (Rossman et al. 1996. The Garter Snakes: Evolution and Ecology. Univ. Oklahoma Press, Norman, Oklahoma. 332 pp.). The largest recorded litter was 26 from a specimen of *T. sauritus sackenii* collected in Florida (Telford 1952. Quart. J. Florida Acad. Sci. 15:175–185). Hulse (2001. Amphibians and Reptiles in Pennsylvania and the Northeast. Cornell Univ. Press, Ithaca, New York. xii + 419 pp.) reported a mean litter size of 11.3 (range 8–13) in a sample of 8 litters from Pennsylvania, but did not indicate which of the two subspecies native to the state were involved. Litter sizes reported for specimens from within the range of *T. s. septentrionalis* include 9 (Bishop 1927. Amphibians and Reptiles of Allegany State Park. New York State Museum. 141 pp.); 6, 9, and 10 (Gilhen 1984. Amphibians and Reptiles of Nova Scotia. Nova Scotia Museum. 162 pp.); and 7 and 9 (Langlois 1924, cited in Ruthven et al. 1928. The Herpetology of Michigan. Univ. Michigan. 229 pp.). Ruthven et al. (*op. cit.*) stated that they counted embryos in "a few specimens and they seem to average about a dozen." Carpenter (1952. Ecol. Monog. 22:235–258) reported an average litter size of 10 from 5 specimens in Michigan. Here, I report an unusually large litter of this subspecies from Erie Co., Pennsylvania, USA.

On 8 July 2007, I captured a gravid female *T. s. septentrionalis* (SVL = 565 mm; total length = 817 mm) in Pennsylvania State Game Land 109. I maintained her in captivity until parturition on 2 August 2007, when she produced 24 live young. There were 14 males and 10 females. Mean SVL of neonates (mean ± SD, [range]) was 156.7 ± 3.98 mm (147.8–163.5), mean total length was 225.9 ± 6.06 mm (214.3–239). The total mass of the litter was 39 g and the female's mass after parturition was 61 g, yielding a relative litter mass of 0.639. Photo vouchers of the female (TREC R-00086) and litter (TREC R-00087) were deposited in the collection of the Natural History Museum at the Tom Ridge Environmental Center. All snakes were released at the point of capture. I thank Brian Gray for useful input on the manuscript.

MARK LETHABY, Natural History Museum at the Tom Ridge Environmental Center, 301 Peninsula Dr., Erie, Pennsylvania, 16505, USA; e-mail: mlethaby@verizon.net.

***TROPIDONOPHIS DORIAE* (Barred Keelback). REPRODUCTION: MAXIMUM CLUTCH SIZE.** *Tropoidonophis doriae* is known from Indonesia (Irian Jaya, Aru Islands) and Papua New Guinea (Malnate and Underwood 1988. Proc. Acad. Nat. Sci. Philadelphia 140:59–201). Malnate and Underwood (*op. cit.*) reported seven clutches of *T. doriae* from New Guinea (mean 5.4 ± 2.0 SD; range: 3–8). The purpose of this note is to report a new maximum clutch size for *T. doriae*.

One female *T. doriae* (SVL = 904 mm) collected 27 January 2004 at Laronu, Central Province, Papua New Guinea (9.44387°S, 147.98383°E, datum WGS84; elev = 880 m), and deposited in the Bishop Museum herpetology collection (BPBM), Honolulu, Hawaii (BPBM 19486) was examined. A ventral incision was made in the lower body wall to expose the reproductive tract. Eleven oviductal eggs were counted which is a new maximum clutch size for *T. doriae*.

I thank Pumehana Imada (BPBM) for facilitating my examination of *T. doriae*.

STEPHEN R. GOLDBERG, Whittier College, Department of Biology, PO Box 634, Whittier, California 90608, USA; e-mail: sgoldberg@whittier.edu.

***TROPIDONOPHIS STATISTICUS*. REPRODUCTION: MINIMUM REPRODUCTIVE SIZE.** *Trophidonophis statisticus* occurs from southeastern Irian Jaya, eastward through the central massif of New Guinea (Malnate and Underwood 1988. Proc. Acad. Nat. Sci. Philadelphia 140:59–201). Malnate and Underwood (*op. cit.*) reported 18 *T. statisticus* females contained 3–9 eggs, of which the smallest female measured 483 mm SVL. The purpose of this note is to report a new minimum reproductive size for *T. statisticus* females.

One female *T. statisticus* (SVL = 415 mm) collected February 2003 at Siyomu Village, Milne Bay Province, Papua New Guinea (10.0171°S, 149.5970°E, datum WGS84; elev. 1300 m) and deposited in the Bishop Museum herpetology collection (BPBM), Honolulu, Hawaii as BPBM 17297 was examined. A rear ventral incision was made to expose the reproductive tract revealing three enlarged eggs > 6 mm length. Four-hundred fifteen mm is a new minimum size for reproductive activity in female *T. statisticus*.

I thank Pumehana Imada (BPBM) for facilitating my examination of *T. statisticus*.

STEPHEN R. GOLDBERG, Whittier College, Department of Biology, PO Box 634, Whittier, California 90608, USA; e-mail: sgoldberg@whittier.edu.

University of California, Berkeley, California, USA
e-mail: wakelab@berkeley.edu

Mesoamerica is a region of megadiversity, with amphibians and reptiles especially well represented. Given the relative size of the region, diversity is extraordinary, yet despite decades of intense fieldwork the fauna is still not fully known. Sadly, this fauna is at great risk of extinction. Human population growth has been extraordinary. Costa Rica, with fewer than 900,000 people in 1950, is projected to have in excess of 5,900,000 in 2025. Mexico, which had fewer than 28,000,000 people in 1950, is projected to have about 130,000,000 people in 2025 (World Resources Institute 2011). These increases, roughly a factor of 5, are characteristic of the region. These dramatic increases in numbers of people are accompanied by rampant habitat modification that is taking a terrible toll. I made my first visit to Costa Rica in 1961, when a trip to Finca La Selva was still an adventure. Finca La Selva was a small, cleared area in a magnificent forest; today The La Selva Biological Field Station *is*, effectively, the forest.

Given the relatively small size of Mesoamerica compared to the great continents, its hepetological diversity is amazing. My favorite organisms, plethodontid salamanders, are especially well-represented. It is surprising enough that nearly 45% of all salamanders are the Neotropical plethodontids, but even more surprising is that 90% of these occur in Mesoamerica. One would like to think that we have a good understanding of amphibian diversity in the region. The message from salamanders is that we should not be so sure. In 1926 Dunn reported 30 species of tropical salamanders (Bolitoglossini). By 1976 the number had increased to 132 (Wake and Lynch 1976). Today 268 are recognized of which 241 occur in Mesoamerica (AmphibiaWeb 2011). This book lists 215, an indication of the rate of discovery and description of new species from Mesoamerica (and I know of more than 25 awaiting description). These are nearly all morphologically identifiable taxa; we are only beginning to appreciate how many cryptic species are yet to be described (Crawford et al. 2010). While distinctive new clades are still being discovered (McCranie et al. 2008), nonetheless it seems likely that we are largely at the stage of filling in details; the main dimensions of the herpetofauna are now known. Frankly, there is too little habitat remaining that has not been at least superficially surveyed for many more major discoveries to be made. Thus, the appearance of this book represents a benchmark in our understanding of the herpetofauna of Mesoamerica and the threats to it.

Following a Foreword by Jim Murphy and a somewhat longer Preface by the editors, the book is arranged in six major sections. Appropriately the first of these, entitled The Global Amphibian Assessment, is a chapter by Simon Stuart, Janice Chanson, Neil Cox, and Bruce Young. The Preface makes clear that this chapter was the first one completed for the book and that some time has passed since it was produced, due to delays in publication. The chapter is based on the 2004 assessment. Nevertheless, it is a nicely produced chapter that remains both useful and relevant.

The second section, by the editors, is a short, workman-like account of recent taxonomic changes. They recognize that this is a moving target. Unfortunately, by listing "previous names" and "present names" they inadvertently validate names that are currently in dispute. For example, debates continue over the content of such taxa as *Bufo*, *Rana*, and even less well-known taxa (e.g., *Hylobates*), and I do not think the authors are sufficiently clear that many such changes are matters of taste rather than rule, and are optional.

The largest and most ambitious section of the book is entitled "Distributional patterns of the herpetofauna of Mesoamerica, a biodiversity hotspot," by Wilson and Johnson. The chapter is more than 200 pages long. Following a well-constructed introduction to the natural setting of Middle America, the authors frame their analysis by recognizing 21 physiographic regions and 15 vegetation zones. They then proceed to categorize 731 species of amphibians and 1,148 species of reptiles with respect to these regions and zones. A key element of their analysis is calculation of a Coefficient of Biogeographic resemblance. They conclude that endemnicity of amphibians is very high, but reptiles, too, show strong endemism, with more than a half of the species endemic to specific countries. It is not surprising that Mexico has the highest levels of endemicity, given its relative size and topographic and historical geological heterogeneity. They also calculate a Coefficient of Habitat

Resemblence, which enables them to argue that Subalpine Moist Forest is most unlike other vegetation zones. This is not surprising to me, because salamander endemics, for example, are highly concentrated in cloud forests. This chapter is filled with tables, but also with words, and it is an impressive accomplishment. The data are up-to-date to the end of 2008. In an addendum they discuss 21 new studies (well into 2010) and discuss how these change their results. This is clearly a moving target and I think it was not worth the effort for such a short term update, given the rate at which publications on this region are appearing.

The remainder of the book is dominated by "country assessments," starting with Baja California, then proceeding from northern Mexico, central highlands of Mexico, southeastern Mexico, Belize, Guatemala, Salvadoran protected areas, Honduras, Nicaragua, Costa Rica, and finally to Panama. In addition to the three editors, authors include 26 people, mostly residents of the countries analyzed. The chapters contain lists of species, current conservation status (CITES, IUCN, and country-specific, where appropriate), environmental vulnerability scores, and occurrence in protected areas, but while there is general uniformity, each chapter has its own unique features. Overall the information content is valuable and the authors have made scattered information generally accessible.

Special conservation topics are covered in six chapters, mostly focused on particular taxa, but one, by Townsend and Wilson, deals with a vegetation type in a particular region (subhumid forest of Honduras). The book concludes with a section labeled "Looking Ahead," a ca. 50 page account by Wilson and Townsend summarizing the contents of the book and presenting a general discussion. A final appendix lists the conservation scores for the entire Mesoamerican herpetofauna. Their prognosis for the future of the unique herpetofauna of Mesoamerica is not very rosy.

Mesoamerica has an enormous herpetofauna, given its relatively small area, and levels of endemism are extraordinary. The book nicely balances analyses of political entities and those of physiographic regions and vegetation types. It was an audacious undertaking, and yet I think the results are substantive and illuminating. Probably most taxa are sufficiently well known (salamanders may be an exception) that the many tables and calculations will prove to be relatively robust.

The book is beautifully produced and it has a highly professional appearance. The individual chapters resemble journal articles in format, each with both English and Spanish abstracts and separate Literature Cited sections. The layout is attractive, the illustrations and photographs (although not numerous) are high quality and uniform in production, and the book is solidly bound with an attractive dustcover. However, the downside is that the book weighs 3.2 kg!

I congratulate the editors and authors for making a permanent contribution to our knowledge of the herpetofauna of Mesoamerica. Every student of the region will want to own this book.

Reviewing books can sometimes be a tedious, dreary task for a scientist, foisted upon us by friendly (or pushy) editors-in-need. Hesitation to take on a book review is usually not so much based on disinterest in the matter presented in the book, but on the fact that there really isn't much "bang for the buck" in writing a book review: who really reads them anyway? Furthermore, considering the time commitment required for making a book review passably entertaining, we might rather spend our valuable time studying a real data set.

The request to review Leslie Anthony's *Snakebit* was different for two reasons, which gave the task an irresistible allure. Firstly, we know this ink slinger and most of his cabal well and, secondly, we are both immortalized in Chapter 8, entertainingly and ominously titled "Another Messy Freak Show." Playing a sufficiently prominent part in someone else's life to end up in "their book" is special, and led to instant agreement on our part to compose this review when approached. Little did we know how this freak show would play out, and we ask the reader's

forbearance if we respond to the author's literary kindness with our own sprinklings of humor.

To place *Snakebit* and its author into a proper context one must first deal with a nomenclatural issue. In professional herpetological circles, popular writer Leslie Anthony is none other than Leslie A. Lowcock, infamous and heretofore thickly mustachioed and otherwise hairy salamander geneticist, winner of the prestigious 1989 American Society of Ichthyologists and Herpetologists' Stoye Award. A search for publications under that name will reveal some fine research that lends Les lasting, indubitable scientific credibility. However, this path essentially terminates with the switch from Lowcock to Anthony, and it appears the herpetologist author of *Snakebit* morphed from passionate scientist to something much more tame and lame, a herp advocate. In fact, Les states that herpetology is his "distant past" (p. 7), one that he "released" (p. 8) some time ago. Despite this temporal break and the unjustified emendation of his name, and with forgiving admiration, his contributions to herpetology are still significant enough for us to accept that the moniker "herpetologist" still applies to Les. We simply marvel at Les's more recent fixation with a wide range of more popular prose, such as detailing adventures in places as divergent as the ski slopes of Scandinavia or the hunting grounds of Anticosti Island, through magazines such as *Powder*, *Skier*, or *Bike* (to name but a few), via an exposé of adventure skiing (and of skiing as an adventure) in his book *White Planet*, or in the interesting short film *Missing*.

Snakebit travels the classic arc of autobiography, from the protagonist's youth to his dotage, prefaced by a chilling experience in Finland that led to the writing of the book. The chapters provide appropriate thematic divisions to Les's story, and each chapter not only gives insights into the man we knew, but cleverly picks up one or more relevant scientific threads. Les masterfully integrates the science with his story and creates an intellectually appealing and entertaining narrative that will be attractive to the scientist and the interested amateur alike. A warning to those considering having their young children read the book, which, for its entertainment value, may be a draw: reality-based, but contextually gratuitous, f-bombs exist.

The trajectory of Les's life begins with a chapter describing the development for his initial interest in herps in suburban Toronto and at Camp Mil-da-ta-ca ("Into the Swamp"). A chapter introducing readers to some key herpetological influences for Les, which also serves as a well-timed introduction to herpetology as a science, follows ("Creepy Critters and Animals, Too"). Chapter 3 ("A Salamander Under a Log") showcases the on-goings in the lab of James Bogart at Guelph University (of particular interest to HK and TFS, since Jim is academic grandfather to us both). "Bulletin from the Pacific" is the story of a Fijian herp adventure with a solid exposé of hybridization, which completes a four-chapter set of what we classify as Les"s pre-professional life.

In the following five chapters, the author tells the story of Les Lowcock, the professional scientist. While this was the time in Les's career that included his greatest scientific contributions ("Slime Buckets"), it was also the time of fairly inane extracurricular activities ("Rommy, Can You Hear Me?"), noteworthy field trips ("A Day in Hell," "Boneheads") with über-scientists like the two Bobs (Murphy from the Royal Ontario Museum and Carroll from the Redpath Museum), and a postdoctoral fellowship ("Another Messy Freak Show"). The first of these chapters might best be summarized (with apologies to *The Producers*) as "Springtime for Leslie and Canada" as Les mud-wrestles hordes of "ambitious amphibian immigrants" (p. 95), salamanders in particular, as they emerge from the Canadian winter and need to be checked for their hybrid status. The chapter also includes a lot of valuable information on amphibian natural history and ancestry, as well as salamander genetics. In the Rommy chapter, Les follows on with a discourse on museum collections made lively by an introduction to his contemporaries at the Royal Ontario Museum. Having traveled widely ourselves, we are not convinced that Baja California is deserving of the chapter title "A Day in Hell," but we appreciated Les's perspective on deserts ("If the continents are the Earth's skin, then deserts are a patch of eczema on its butt." p. 132). We also applaud his insightful comments on biogeography, lizards, and the ancestry of birds. These are continued in "Boneheads" with well-placed paragraphs on fossils and the origin of snakes. The style of popular writing displayed in these chapters is probably why Les does so well outside the world of scientific journals. It is informative and captivating.

We separate out the chapter titled "Another Messy Freak Show" here since this is where Les includes us in his story. Doubtless, some interesting things did happen two decades ago, but memories can be deceiving. It is therefore with keen interest and satisfaction that we note the "Oprah Clause" on the book's dedication page, stating that in this book "anything to do with people is as close to true as the subjectivity of experience and the unconscious temptation to exaggerate will permit." We believe it likely that, as a result of an already addled brain, the "subjectivity of experience" failed Les. Characterizing TFS by a purported penchant for "hockey, hash, beer, and women" (p. 152) and HK as "Der Kaiser, [...] a cartoon character passing steam through his ears" (p. 159) could, in some circles, be considered unflattering. In the spirit of literary freedom, we understand these humorous depiction as more fiction than fact. We are convinced that neither the computer smash-up (HK was an early Apple adopter and used Macintosh computers even then, and there were definitely no old Mac parts anywhere in the PC-besotted museum) nor the frog-in-pee-snowglobe (even before getting a PhD, HK could tell "his" new species, a dendrobatid, from the eleutherodactylids of his research focus despite the purported tagging shenanigans) ever happened. We are happy to report that TFS repaid the soggy chair cushion in kind nearly two decades later at his office in Germany (TFS is the "former colleague" on p. 81). HK is still looking for a suitable snowglobe to fill and mail. Oprah Clause, indeed.

The remaining five chapters mostly form the Leslie Anthony component, or what may be considered the post-professional time of the story arc. Key episodes include additional fieldwork, in Vietnam ("Saving the World One Jungle at a Time"), Armenia ("Saving the World Redux"), the snake pits of Manitoba ("Ode to a Gartersnake"), and the Okanagan of British Columbia ("Riesling and Rattlesnakes"). "Geeks Like Us" introduces the reader to the discourse at scientific meetings, with particular mention of the early discussions about amphibian declines, with which Lowcock the Professional was intimately familiar in the Canadian context. Overall, the combination of science and storytelling is quite compelling and beautifully executed. Having now outlined the book in its entirety, let us be forthright and thank the two Finnish *kyy käärme* (*Vipera berus*) for leading Les onto the path of this autobiographical enterprise.

Of course, there are a few quibbles. In the first place, regarding the book's title it is unclear to us what Les is "confessing"—unless he is seeking absolution for occasional pranks that may not have been enjoyed equally by the prankees. We were also wondering why the snakebit poet-herpetologist would choose

cover art that, while doubtlessly meritorious, does not accurately depict its serpentine subject (we note with pleasure that this has been nicely remedied in the paperback). We found exactly two typos (p. 170: "Caldwell, Sharbel, Carroll, and me" instead of "and I"; p. 276: "Brughuel" should be "Brueghel") and want to note that the Grateful Dead did not play their unforgettable concert in Berkeley but in the Shoreline Amphitheatre in Mountain View (p. 237), where we were all enlightened by some serious second-hand smoke. Taxonomic quibbles are only minor (*Vipera* vs. *Pelias*, *Laudakia* vs. *Agama*, *Dolichophis* vs. *Hierophis*). We also take exception to the statement that "[animals were] waiting in the fridge for a governor's reprieve" (p. 61), since Canadian provinces are governed by Premiers and, at last accounting, Ontario was still a Canadian province. Furthermore, Cuban treefrogs, coquís, and Amazon forest frogs would have died in Jim Bogart's fridge and must have made their last home somewhere else. Lastly, it is incorrect to state (p. 102) that frogs of the genus *Eleutherodactylus* are the only vertebrate genus with a member in amber, as such specimens are also known for Hispaniolan *Anolis*, European lacertids, and geckos from three continents. All of this means that whereas the post-Lowcock Anthony *is* capable of scientific accuracy in listing by Latin binomials 13 species of salamanders, 20 frogs, 16 lizards, 10 turtles, 3 crocodilians, and 56 snakes, he nevertheless *is* a post-Lowcock Anthony.

The foregoing notwithstanding, nothing can detract from the genius of Les's writing. To use herpetological hyperbole, if David Dennis is the Robert Bateman of herpetology, then Leslie Anthony may be its Bard. How else does one explain flowing alliterations like "bevy of bewildered wildlife" (p. 12), "susurration of something sliding through grass" (p. 14), "dalliance of the decadent and deadly" (p. 250), or "As I wandered, waded, and wallowed, my nostrils flared daily with the pungent miasma of ... the Chthonic Domain" (p. 54). Who else could come up with "[The snake] brushes me with flickering tongue as a lover might" (p. 27), "[herpetology, a] lascivious vixen, with [a] dangerous embrace and many whispered secrets" (p. 167), or "the Trans-Canada Highway, [...] with the thawing carcasses of a zoo's worth of winter roadkill, draped on the shoulder like toys kids had shaken the stuffing out of and tossed from the car" (p. 218). Where else have herpetologists been exposed to new word creations like "the snake waterfalls between my hands like a slinky" (p. 27)? Since when is "waterfall" a verb? "Inculcated" (p. 133) or "mountebank," anyone? And then there are the plentiful, simply elegant expressions that convey in few words a fabulous image, such as "46 chromosomes ... lounging around in the nucleus in a great, unconcerned tangle" (p. 67), "Baja's deconstructionist landscape" (p. 137), "a bag of snakes can be a powerful carnet" (p. 139), and "Yerewan slid by like an unfinished basement" (p. 273). Given the magic of the writing, the book really ends too abruptly. Maybe we just wish for a reflective chapter so that the poetic journey through Scrabble didn't have to end so soon.

In approaching this review, we were initially mildly put out because of our own portrayal. However, we are content to allow Les his little bit of Oprah Clause-protected fiction in view of the undisputed service *Snakebit* does to bring some higher-level prose to herpetology. Just as *The Economist* magazine is capable of the twofer of excellence in news and writing, so Les is able to weave an appealing tale of solid scientific substance and choice composition (witness our feeble attempt at alliteration). Buy the paperback, because it has a real snake on the cover, and enjoy the read.

There is no denying the fact that México has become a world leader in assessing and conserving its herpetofauna. This is certainly due to remarkable growth in the number of professionally trained native herpetologists, along with the continued interest by international researchers, especially from the United States and Europe. Furthermore, several national and state organizations (e.g., Sociedad Herpetológica Mexicana, ECOSFERA, CONABIO, among others), including academic institutions, have been actively supporting and funding herpetological research projects on a state, regional, and national scale. *Amphibians and Reptiles of the State of Querétaro, México*, is one of the latest state oriented books, coauthored by two prominent herpetologists who have been investigating Mexican amphibians and reptiles for many years. James R. Dixon, now Professor Emeritus at Texas A&M University, along with many of his students, began visiting México around 1957 and was one of the first to begin assessing in detail the herpetofauna of Querétaro, the results of which formed a good portion of the baseline data used in the present volume. Julio A. Lemos Espinal is a Research Professor in the Laboratorio de Ecología of the Unidad de Biología, Technología y Prototipos de la Facultad de Estudios Superiores Iztacala UNAM. He has been studying the herpetofauna of northern and central Mexico and is well known for coauthoring, along with Hobart Smith, volumes on the amphibians and reptiles of Chihuahua, Coahuila, and Sonora. No two herpetologists were better suited for producing a book on the herpetofauna of Querétaro.

Amphibians and Reptiles of the State of Querétaro, México, is hardbound with a dust jacket and reasonably constructed for durability. It is bilingual in Spanish and English, most of which is divided by language in separate sections of the text. The introduction includes sections on historical herpetological perspectives, a description of the climate, geography, vegetation, an explanation of sections within species accounts, and a list of the current amphibians and reptiles known from the state. The bibliography,

maps (districts, topography, vegetation, and climate), photos of physiographic features and species (Appendix 1), gazetteer with mapped localities (Appendix 2), distribution maps (Appendix 3), and locality of collection (Appendix 4) are located near the end of the volume after species accounts. Accounts for the 117 listed species (29 amphibians, 88 reptiles) known from Querétaro are prefaced by descriptions of class, order, and family, and species accounts include sections on explaining title information ("title" here referring to scientific name, original author and date of original publication, and allocation to genus), common name, identification, morphology, coloration, distribution, habitat, behavior, diet, taxonomy, etymology, protected status, and references that are separate from the bibliography section located after the species accounts. The protection status section is based mostly on the classifications published in 2002 by Secretaria del Medio Ambiente y Recursos Naturales (SEMARNAT). Needless to say, the volume contains tremendous amounts of information not only gleaned from the literature, but most obviously from personal experiences by the authors. This is an essential book for anyone, including professional and amateur herpetologists, interested in the herpetofauna of Querétaro in particular and México in general.

The layout for the volume is good, although it would have been easier to use if the municipality, topography, vegetation, and climatic maps were placed closer to the section where they are discussed, but I suspect the placement was a publisher decision. There are a few minor typographical errors in the text, but none cause confusion. A very useful aspect of the species accounts are the dichotomous keys preceding each group, with depictions of valuable indentifying characters and figures of some species placed at appropriate positions within the keys.

The species accounts also include the "most important references" pertaining to each species, although it would have been helpful to the reader if a taxonomic cut-off date would have been designated in the introduction section to clear up any confusion of what literature sources were available for citation. That particular point leads to a related issue prevalent in not only the volume reviewed here, but in many recent comparable publications conveying significant taxonomic information. The issue is the lack of taxonomic synonymies being identified by literature sources, which if present would have aided readers unfamiliar with nomenclatural history. This is especially important today because of the large number of recent phylogenetic studies that have changed long established family and genus names (see Johnson et al., 2010 for a list of changes). In the case of the present volume, the following are pertinent (present names first followed by older names in brackets): *Anaxyrus*, *Incilius*, and *Rhinella* or *Chaunus* [*Bufo*]; *Craugastor* [*Eleutherodactylus*]; *Eleutherodactylus* [*Syrrhophus*]; *Ecnomiohyla* and *Scinax* [*Hyla*]; *Lithobates* [*Rana*]; *Spea* [*Scaphiopus*]; Scaphiopodidae [Pelobatidae]; Dibamidae [Anelytropsidae]; Corytophanidae, Phrynosomatidae, Polychrotidae [Iguanidae, in part]; *Plestiodon* [*Eumeces*]; *Aspidoscelis* [*Cnemidophorus*]; *Pantherophis*, *Pseudelaphe*, and *Senticolis* [*Elaphe*]; and *Rena* and *Epictia* [*Leptotyphlops*, Adalsteinsson et al., 2009]. The primary taxonomic rank of all accounts is noted as being at the species level, although the authors do comment on subpecies in several instances, a practice that in my opinion is outdated in modern phylogenetic systematics. In general, the taxonomic status of most species is up-to-date, although the authors chose to use a few names, without comment, that are contentious: *Norops* vs *Anolis* (Poe 2004) and *Coluber* vs *Masticophis* and *Rhinella* vs *Chaunus* (both discussed in Wilson and Johnson 2010).

A few major references are cited in different sections of the species accounts, although a small number were inadvertently left out of the reference section and were also not listed in the bibliography (e.g., Jameson, 1950 – *Craugastor augusti*; Roth, 1972 – *Hyla arenicolor*; Iverson and Berry, 1979 – *Kinosternon integrum*; Smith et al., 2008 – *Plestiodon tetragrammus*; Slevin 1942 – *Ninia diademata*; Goldberg, 1998 – *Oxybelis aeneus*; Anderson, 1960 – *Storeria storeroides*).

The range maps (Appendix 3) use dots to identify species locations listed in the locality of collection section (Appendix 4), but in at least one instance (*Chiropterotriton magnipes*), the distribution description in the species account does not match the mapped localities (Map 13) or collecting sites (Appendix 4).

There are 227 color photographs of varying quality for listed species (several with multiple photographs); there are no pictures for 17 forms. Several photographs were of individuals found as far away as Arizona, Texas, Chihuahua, Durango, Sonora, and in one case, from an exotic individual from Peru (*Hemidactylus frenatus*). It would have been more supportive if at least one photograph of species not pictured, even from a distant locality, were included in place of one from a species depicted multiple times. Many of the 17 species are not necessarily rare throughout their ranges, so a photograph of some of those may have been available from an outside source. Of course, the best photographic scenario would have depicted individuals from Querétaro, because geographic variation within wide-ranging species creates the possibility of showing an individual not typical of those found within the state. It would also have been better if all photographs would have identified both the sex and locality of portrayed individuals instead of listing them for some, but not for others.

In summary, the few weaknesses in the book do not overly influence its value to those interested in an information source with taxonomic keys and photographs of the amphibian and reptiles of Querétaro, México. The $85.00 price tag, which might seem high to some, is comparable to other hard-bound books on related herpetological subjects. I highly recommend *Amphibians and Reptiles of the State of Querétaro, México*, to professional and interested amateur herpetologists or to any wildlife enthusiast who wants to learn about the herpetofauna and natural landscape of a fascinating region of México.

The Snakes of Honduras — Systematics, Distribution, and Conservation

By James R. McCranie. 2011. Society for the Study of Amphibians and Reptiles (www.ssarherps.org). 724 pp. Hardcover. US $95.00. ISBN 978-0-916984-81-6.

SEBASTIAN LOTZKAT
Senckenberg Forschungsinstitut und Naturmuseum Frankfurt, Senckenberganlage 25, 60325 Frankfurt am Main, Germany
e-mail: slotzkat@senckenberg.de

Given the astonishing species richness of tropical herpetofaunas, even the baseline exploration and documentation of their diversity is a laborious and time-consuming task. This holds equally true for the best-studied fraction of the neotropical realm, Central America. Notwithstanding the comparably small surface area of its nations, more than two centuries have passed since the first descriptions of amphibian and reptile species until, only during the last decade, the first truly detailed treatments (i.e., works that address various aspects of each species' biology and extend well beyond the scope of mere identification guides) of herpetofaunal groups at the country level could be compiled.

One such milestone summarizing all available information for a higher taxon within one country was *The Amphibians of Honduras* by Wilson and McCranie (SSAR Contributions to Herpetology Vol. 19, 2002), which has set a high standard in many ways. Now Randy McCranie has released its worthy successor, *The Snakes of Honduras*. This opus follows the format and concept of the amphibian book and constitutes a comprehensive scientific account of all 136 snake species known to occur within the country. The book is slightly more voluminous than its predecessor and, with 724 7x10-inch pages, is too bulky to carry around in the field. But that is not the purpose of this reference work.

Following a foreword by Jay M. Savage and a preface by the author, the Materials and Methods section introduces the structure of the species accounts and coherently explains how the data were obtained, processed, and presented. Readers will be pleased to learn that all content is updated to July 2010. They will be awestruck by the firm footing of the morphological and biogeographical data; as many as 6160 specimens were examined by the author, who has personal field experience with 90% of the species!

The introductory chapter on the Honduran environment is a revised update of its analogue in the amphibian book, detailing general information as well as the country's complex physiographic and climatic setting. The author places special emphasis on the nine general forest formations, including their respective distribution, climate, typical vegetational characteristics and important subtypes, snake diversity and conservation status. The maps in this chapter introduce the reader to the uncomplicated, concise map format employed consistently throughout the book.

After a brief history of reptile research in Honduras, the reader is introduced to the composition of the Honduran snake fauna, and provided with a key to the nine families known to occur in the country. Dichotomous keys to the 67 genera and 136 species are placed preceding the respective taxa. Each key is accompanied by an exact Spanish translation, allowing for the determination of any Honduran snake at hand to species level by anyone. The elaborate keys are perfectly practicable owing not only to the characteristics employed, but especially to their illustration; every distinctive feature is excellently clarified by accompanying drawings or photos and their truly informative legends.

The 136 species accounts themselves and the interspersed keys comprise almost 500 pages, leaving virtually nothing to be desired. After references to the original description and type specimens, synonyms applied to Honduran material are listed. The overall distribution as well as that within Honduras are given along with a map of actual collection localities. The in-depth descriptions of external morphology, hemipenes, as well as coloration in life and in preservative are almost exclusively based on explicitly listed specimens from Honduras, complemented with and compared to data from other countries where sensible. A short diagnosis leaves almost no possibility to confuse the respective species with similar ones occurring in Honduras. One highly appreciated feature is the illustration list, which is not limited to mere references, but actually specifies the content of the itemized figures. The obligatory remarks paragraph is succeeded by comments on natural history that include data from outside Honduras. After a brief explanation of the scientific name's etymology, the author concludes each species account by listing the specimens he has examined personally, as well as other reliable records plotted on the respective distribution map. The book's core section ends with a quick mention of four species reasonably expected to occur in the country.

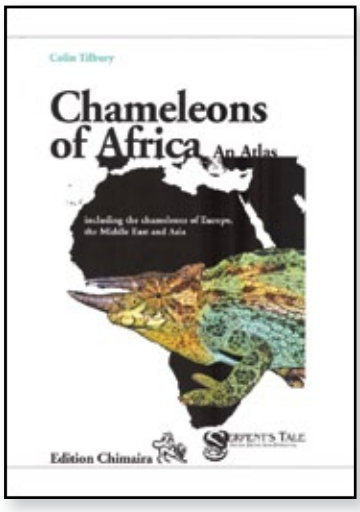
The following biogeographical analysis scrutinizes the distribution of the Honduran snake fauna among political, physiographical, ecological, and historical units, revealing broad patterns as well as examples of endemism and distributional end points. Subsequently, the conservation status of all native species is assessed by analyzing population trends and known occurrences within protected areas, and the calculation of Environmental Vulnerability Scores and IUCN categories. Against the country's sociocultural and economic background, this thorough assessment necessarily draws a rather pessimistic picture of Honduras' environmental future as a whole—reason enough for the author to call for more biodiversity research coupled with actual enforcement of the existing environmental legislation by the hitherto rather passive authorities in charge. Yet, McCranie kindly offers his reader a little comfort by providing a very personal epilogue that is guaranteed to raise a smile on the face of anyone who has spent field time in the Neotropics.

Approximately 180 well-labelled color photographs exemplify major snake habitats and depict 132 of the species discussed, overwhelmingly showing specimens from Honduras.

Close to its end, yet another treasure of its own within this work is the gazetteer detailing not only the localities mentioned in the species accounts, but every single herpetological collection site known to the author within Honduras—most valuable

for anyone who works on Honduran biogeography. A glossary defining the terminology and abbreviations used throughout the text, references, and indices to both scientific and authors' names complete this work.

Probably the only drawback of this magnificent book is the photographs, many of which should have been further processed to appear a little clearer in print. Beyond that, one can hardly find anything to animadvert in this opus. Like its predecessor, *The Snakes of Honduras* is a meticulous, encyclopedic study of a complex and species-rich herpetofaunal group at the country level. Owing to over 30 years of research by the author and his companions, the book is bursting with clearly structured, reliable information resulting in a final product that is unparalleled within the realm of Latin American herpetology.



Taking into consideration the numerous publications by the author and his colleagues, one is bound to agree with McCranie's preface statement that they "have come close to achieving the goal of documenting the distribution and content of the Honduran herpetofauna." Indeed, Honduras will be the first country in Central America having its herpetofauna described in such detail once the equivalent treatment of the remaining reptile groups, which is already in preparation, is published. This final book will be much anticipated by members of the herpetological community who appreciate, work with, and rely on *The Amphibians* and now *The Snakes*.

Chameleons of Africa. An Atlas including the Chameleons of Europe, the Middle East and Asia

By Colin Tilbury. 2010. Edition Chimaira, Frankfurt am Main (www.chimaira.de). Hardcover. 831 pp. EUR 98.00 (approx. US $140.00). ISBN 978-3-89973-451-5 (in the US available at Zoo Book Sales, www.zoobooksales.com).

e-mail: w.boehme.zfmk@uni-bonn.de

This voluminous book by Colin Tilbury in the Chimaira "white series" is a remarkable summary of knowledge about chameleons. However, despite the thickness of the volume only the species occurring in mainland Africa, southern Europe and Asia are included (the distinction between the Middle East and Asia in the title is, of course, unnecessary because the Middle East *is* part of Asia). If the author would have also included the species of Madagascar and the Indian Ocean islands, then this would indeed have much exceeded the possible number of pages for such a project, and a second volume would have been necessary. However, it is with the African continent that Colin Tilbury is most familiar and it is there that he carried out numerous excursions in order to take his own photographs in the field of as many species as possible. Generally, this geographic delimitation makes sense because Africa (including southern Europe, the Near East and southern Asia) and Madagascar harbor distinct evolutionary lines (genera in the taxonomic sense) of these most bizarre lizards. Only very recently, after the publication of this book, has it been revealed that the Seychelles might have better been treated with mainland Africa. The endemic Seychellean chameleon, now placed in the resurrected genus *Archaius* (Townsend et al. 2010) and formerly thought to be part of the Madagascan genus *Calumma*, is in fact sister to the East African dwarf chameleons of the genus *Rieppeleon*.

This example demonstrates how fast the current knowledge about chameleon species diversity is growing. Tilbury's book lists 102 currently recognized species from the non-Madagascan realm, whereas the checklist by Klaver and Böhme (1997) listed only 57 species for the area covered by the present book. This is nearly a doubling of the species number in just 13 years! Tilbury's count would have even been a bit higher if he had followed another species concept concerning the *Chamaeleo dilepis* complex within which, for example, the taxa *quilensis* and *roperi* are often considered to be good species by other authors (myself included). Although his species count includes a good number of recently elevated subspecies (e.g., in *Bradypodion* or in the *fischeri* group of *Kinyongia*), it is out of date due to the continuing discovery and recognition of new species. In some instances the increase of species is of course due to (1) the elevation of former subspecies as mentioned above, or (2) to the resurrection of synonyms, but (3) formerly unknown, truly new species are among this number as well. An example of the first case is *Trioceros perreti*, *T. serratus* exemplifies the second, and *Nadzikambia baylissi* as well as *Trioceros hanangensis* (Krause and Böhme 2009; Barej et al. 2010; Branch and Tolley 2010) are novelties.

It must be noted, that with respect to taxonomy, Tilbury has not restricted himself to compiling the systematic literature on chameleons, rather he has contributed significantly to the discovery and description of many new species, e.g., *Rhampholeon acuminatus*, *R. beraduccii*, *R. chapmanorum*, and *R. viridis* and the spectacular tree chameleons *Trioceros balebicornutus*, *T. conirostratus*, and *T. marsabitensis*.

What makes this book more exceptional are its illustrations. Colin Tilbury, who was already well-known for his brilliant photography, travelled through many parts of Africa in order to get his own photographs of common as well as rare species, and the result of this great effort is the impressive visual impact of this atlas of Africa's chameleons. It is, of course, also expected that an atlas will contain distribution maps, and this book does not disappoint: point distributions plotted on colored relief maps not only show the records where a species has been found but also provide information on whether this is a mountain or lowland, savanna or forest species, etc. Biogeographic patterns can be deduced from the maps: widespread vs. relictual, confined to the Rift Valley or the Cameroon highlands, etc.

On the other hand, this book exceeds the requirements of a distributional atlas because it provides also much general information, not only on the individual species, but also on this lizard family as a whole, starting with locomotion, vision, color

change, and many other general aspects, including some very interesting, but so far largely unstudied issues such as the strange buzzing behavior as an aposematic strategy and/or means of intraspecific communication; or the foul-smelling oral glands as a repellent and/or chemical bait which, if confirmed, would be unique in squamates.

Each species chapter, after giving the scientific, English and (if known) local name as well as the relevant synonyms and chresonyms, provides an exhaustive description also covering lungs, hemipenes, and karyotypes (these three character sets have previously been used for systematic purposes), sexual dimorphism, and colour pattern, followed by a listing of key distinguishing characters. These key characters are often accompanied by line drawings, most of which have also been prepared by the author himself. This is followed by a paragraph on distribution, linked to the relevant map, and finally ecology is dealt with by accounts treating habitats, natural history, reproduction, and conservation. A list of specific references concludes each species chapter.

It is not surprising that this enormous amount of information contains some errors, some of which could have easily been detected during proof-reading. For instance (p. 214) the head drawing of *Rieppeleon brevicaudatus* is still assigned to "*Rhampholeon*" *brevicaudatus*. The dot map for the genus *Chamaeleo* as a whole places a few dots where no populations of *Chamaeleo* (nor any other chamaeleonid) exist, e.g., in Albania or the Canary Islands (in the latter case only translocated single individuals are known and these were not even mentioned by Pleguezuelos et al. 2002; see also p. 475). But if accidental introductions of single individuals seem worth mentioning to Tilbury, he might also have cited the records published from the Caucasus area in western Georgia (Chkhikwadze and Bakradze 1993). On the other hand, Mauritania is devoid of mapped records although these are mentioned in the text (see Fig. 563 and map on p. 537). Figure legends 495 and 496 (*Chamaeleo chamaeleon*) read *C.* "*chamɛleon chamɛleon*" and *C.* "*chamaleon chameleon*" which is a bit more problematic than a simple misprint because it involuntarily creates a new "in error" synonym of the taxon. In the reference section, some citations are duplicated, e.g., Hofer et al. on chameleons in Cameroon; in other cases multi-authored papers precede citations of the first author alone (e.g., Klaver). But such faults are really rare in proportion to the total of 831 pages!

In two cases, new taxa discovered after the appearance of this book are already figured under other names: *Kinyongia uthmoelleri artytor* (figs. 439, 440–443) from the South Pare Mts. (Lutzmann et al. 2010) as a typical *K. uthmoelleri,* and *Trioceros hanangensis* from Mt. Hanang (Krause & Böhme), as *T. sternfeldi* (figs. 769, 770). A further taxonomic comment has to be made in respect to the restriction of formerly vague type locality designations, as done in this book with *Bradypodion gutturale* and *B. ventrale*. This procedure is not covered by the Code of Zoological Nomenclature (ICZN 1999), since such restrictions or redesignations of type localities may be only made together with designations of neotypic specimens individually bearing such new and precise locality data.

Some aspects can also provoke stimulating discussions: In the etymology section of the systematic paragraphs, here for the genus name *Chamaeleo* (formerly also *Chamaeleon*, p. 467), one finds a repetition of the old interpretation of Greek "chamaí" (on the soil) and "león" (lion), in the present book "earthlion," which—except for *C. namaquensis* and the likewise ground-dwelling dwarf chameleons of the genera *Rhampholeon* and *Rieppeleon*, all of which are unlikely to have been known to Aristotle and the ancient Greeks—does not really not make sense for these highly arboreal creatures! More plausible to me is the alternative, but largely overlooked or even forgotten interpretation given already by Keller (1913) who derived the name of these creatures (which actually can form a hump with their dorsal line when resting) from the Hebrew word for camel, viz. gamal, with the Arabian diminutive ending "-ún" which reads gamalún, i.e., a little camel. Tilbury's book contains many photographs showing chameleons in this position, e.g., figs. 467, 473, 474, 479, 482, 490, 505 (all from the *C. chamaeleon* group).

An unfortunate bit of information must be added for one of the rarest species: the recently discovered *Kinyongia vanheygeni* was known from the single holotype and one additional living male specimen which was not collected (Neças 2009). The catalogue number for the holotype (ZFMK 88383), cited in this book, had to be provided to the author, due to time pressures with manuscript submission, before the specimen physically reached the collection. When it was finally sent it was lost in transit and never reached the Museum Koenig in Bonn (P. Neças, pers. comm.). As if Colin Tilbury would have foreseen this misfortune, he fortuitously figured the unique living male of *K. vanheygeni*, photographed by E. van Heygen, no less than four times.

In summary, Tilbury's "Atlas" is a true handbook with lots of useful general and specific information on the African and Asian representatives of this fascinating Old World lizard family. It is even more impressive when one takes into account that its author was never paid for his herpetological work. As a medical doctor by profession, he is an illustrious example for what a herpetological "amateur" is capable of contributing to our science.

Frogs: The Animal Answer Guide

By Mike Dorcas and Whit Gibbons. 2011. The Johns Hopkins University Press (http://press.jhu.edu). Softcover. xiii + 160 pp., 16 pp. pls. US $24.95. ISBN 978-0-8018-9936-2.

HEATHER M. HEINZ
Biology Department, San Diego State University
5500 Campanile Drive, San Diego, California 92182 USA
e-mail: hheinz@rohan.sdsu.edu

The Johns Hopkins University Press "Animal Answer Guide" series includes recent books on fishes (Helfman and Collette 2011), rabbits (Lumpkin and Seidensticker 2011), and small wild cats (Sanderson and Watson 2011). This excellent volume, covering frogs worldwide, is second in the series to be co-authored by Gibbons, following the similarly-arranged *Turtles: The Animal Answer Guide* with Judy Greene (2009).

Structured as a series of questions and answers grouped by topic, this book begins with "Introducing Frogs" ("What are frogs?" "When did frogs evolve?" "What other types of amphibians are there?") and moves through chapters on coloration, ecology, reproduction and development, and so on. Three chapters cover human-frog interactions, including "Frog Problems" from a human viewpoint. Anurans get the last word with the chapter "Human Problems," which clearly highlights the decline of these animals, touching on pollution, habitat destruction, chytrid infection, climate change, and the synergistic effects of these threats combined. The final chapter covers the how and why of "Frogology," offering an inside look into the world of herpetological research.

Answers are in-depth enough to satisfy curiosity and perhaps spark further investigation by the intrigued reader. Additionally, primary research is occasionally cited throughout, serving as a welcome introduction to how scientists know what they know.

Over 120 questions are answered in manageable sections of one to several paragraphs in length. While the question-answer format can sometimes be repetitive if reading the book straight through, the overall result is that most answers are complete and self-contained. The book thus lends itself to being a handy reference for the intended lay audience.

Sentences are generally short, clear, and easily read and understood, expanding the book's appropriateness to younger audiences. There is no glossary, however, and the authors have sometimes elected to use a more difficult term when a simpler one might have sufficed (ingested instead of eaten, etc.). Further, technical terms such as aestivation, "sex recognition" and "simple Mendelian inheritance" are sometimes mentioned without explanation and are not always included in the index for cross-reference. Key terms are italicized, somewhat inconsistently, and would have been the natural starting list for forming a glossary.

There is a geographic emphasis on frogs in the United States, but the authors often mention European counterparts of common species and also discuss the more intriguing and unusual anurans of Africa, Australia, South America, and Asia. Despite including a chapter devoted to "Frogs in Stories and Literature," the discussion of traditional or cultural use of frogs is fairly limited apart from the consumption of frogs' legs and the use of poison dart frog skin secretions. Frog lore is largely concerned with western cultures, including modern pop culture references and the re-telling of several frog short stories and jokes.

Many fine photographs are included, liberally placed through the book in black and white. Additionally, sixteen pages of color plates showcase a variety of anurans, both familiar and lesser-known. The color portraits are aesthetically pleasing but fall short of their potential informativeness. The plates are not numbered and are not referred to in the text, even when they could have served to illustrate a concept discussed. Unlike those of the black and white images, the color figure captions do not even briefly mention concepts or behaviors illustrated, such as amplexus. There remains plenty of white space on the color plate pages where such information might have been provided. Additionally, a few of the color portraits might have been moved to the black and white pages in exchange for images that would have benefited from inclusion in the color plates. For example, the visual impact of a leucistic frog sitting on moss is reduced when the entire image is rendered in shades of gray.

Unlike other books in the series, no maps or illustrations are included where a few may have been educational. For example, an illustration of select Gosner stages (Gosner 1960) might have been appropriate for "How fast do frogs grow?" or perhaps a cutaway view of how a frog uses its eyes to assist in swallowing food in the discussion of "Do frogs chew their food?"

Given the target audience, discussion of taxonomy is left deliberately simple. Scientific names follow traditional taxonomy. An appendix references common species to their equivalents as indexed by the Amphibian Species of the World Database (Frost 2009). Another appendix lists internet resources, scientific and conservation societies, magazines and journals, and zoos with a focus on frogs and toads, all useful stepping stones for the lay person looking for more information.

It is easy to imagine this volume resting comfortably in the library of a high school biology teacher or on the shelf of a student who shows a budding interest in herpetology. It would likewise serve as a handy reference for the dedicated herpetologist who fields questions from non-specialists, for it is easy to direct inquiring minds to this book for succinct and accurate answers to common questions, up to and including a judicious response to the inevitable inquiry about toad-licking. Most importantly, this informative book deserves to be in the hands of the interested public, the non-scientists who stand to learn the most about the intriguing biology of anurans as well as their plight in a world increasingly modified by humans.

A hardcover edition of *Frogs: The Animal Answer Guide* (ISBN 978-0-8018-9935-5) is available for US $45.00. A version for the Kindle electronic reader is available from www.amazon.com for US $14.97.

Eagle Mountain PUBLISHING, LC

ANNOUNCES

Cheap HERP BOOKS

We recently opened Cheap Herp Books, a new division of the company through which we are offering a large selection of herpetological books, reprints, and magazines at discount prices. Nearly all of our inventory is in new or "like new" condition.

New items are arriving periodically (e.g., "bundles" of reprints from various museums are now available), so you might wish to visit our website from time to time.

A new addition to our website is that we posted **free PDFs of all the chapters in *Biology of the Vipers*** (2002: edited by Gordon W. Schuett, Mats Höggren, Michael E. Douglas, and Harry W. Greene), a book that has been out-of-print for several years.

INFORMATION FOR CONTRIBUTORS

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes concerning the study of amphibians and reptiles, as well as book reviews, commentaries, regional and international herpetological society news, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (for information, please refer to: http://www.ssarherps.org/pages/JHinstr.php). To submit a manuscript to ***HR***, please consult the SSAR webpage at:

<http://www.ssarherps.org/pages/HRinfo.php>

REPRINTS AND PAGE PROOFS

Reprints of notes or articles published in ***HR*** may be ordered through EZReprints (EzReprint@odysseypress.com), an online reprint ordering system. Authors will receive email notification as the issue goes to press. Page proofs are sent electronically to authors of all articles, book reviews, and obituaries, but are not sent for natural history notes or geographic distribution notes. Proofs are sent as pdf files approximately 2–4 weeks prior to publication. Corresponding authors who are current members of SSAR will automatically receive free, screen-resolution pdf files of their articles or notes.

ADVERTISING

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR web page (http://www.ssarherps.org/pages/HRinfo.php).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Central Michigan University, Department of Biology, 217 Brooks Hall, Mt. Pleasant, MI 48859, USA. Periodicals postage paid at Mt. Pleasant, MI 48859 and at additional mailing offices.

All rights reserved. No part of this periodical may be reproduced without written permission of the Editor, except that authors and their agents are permitted to reproduce and distribute their own articles and notes.

POSTMASTER: Send address changes to Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, UT 84158. **MISSING OR DAMAGED ISSUE?** Please notify Breck Bartholomew, SSAR Publications Secretary (e-mail: ssar@herplit.com) for a replacement.

SSAR PUBLICATIONS

SSAR publishes seven different series: *Journal of Herpetology, Herpetological Review, Facsimile Reprints in Herpetology, Contributions to Herpetology, Herpetological Circulars, Herpetological Conservation*, and the *Catalogue of American Amphibians and Reptiles* (see below for CAAR details). SSAR members receive prepublication discounts on all *Facsimiles* and *Circulars* and on volumes in the *Contributions* and *Herpetological Conservation* series. A complete pricelist of Society publications is available at: http://www.ssarbooks.com/.

CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available for purchase from the SSAR Bookstore (http://www.ssarbooks.com/). Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1–880	check website below for current pricing
INDEX TO ACCOUNTS 1–400: Cross-referenced, 64 pages	$6
INDEX TO ACCOUNTS 401–600: Cross-referenced, 32 pages	$6
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)	$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)	$35
INCOMPLETE SET: NUMBERS 1–190	$75
191–410	$85
411–840	$320

To order: make checks payable to "SSAR" and mail to Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, Utah 84158, USA (fax 801/453-0489). e-mail: ssar@herplit.com. Online orders at: http://www.ssarbooks.com/.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

www.ssarherps.org

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology,* and its news-journal, *Herpetological Review*, both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*.

To join SSAR or to renew your membership, please visit the secure online ZenScientist website via this link:

http://www.ssarherps.org/pages/membership.php

Future Annual Meetings
2012 — Vancouver, British Columbia, 8–14 August (with World Congress of Herpetology)
2013 — Albuquerque, New Mexico, 10–15 July

FURTHER NEW DEVELOPMENTS IN SSAR

Change is coming quickly to SSAR. As I reported to you in March ("A Vision for SSAR's Future," *HR* 42: 1), SSAR is now undertaking sweeping changes in its publications and programs. I have just come from the society's meeting in Minneapolis, held jointly with the American Society of Ichthyologists and Herpetologists, Herpetologists' League, and the American Elasmobranch Society (as the annual Joint Meeting of Ichthyologists and Herpetologists—"JMIH"). Several SSAR events of interest occurred during this meeting and I wanted to give our members the highlights (Society Secretary Marion Preest's detailed report will appear in the December issue of this journal, as usual.) Responses to the dramatic changes in our two quarterly journals, *Herpetological Review* and *Journal of Herpetology*, have been overwhelmingly positive and the editors, Robert Hansen, Erin Muths, and Gad Perry, received widespread and well-deserved congratulations in Minneapolis. The journals look great and mailing them together represents a real financial savings for the Society.

PHOTO BY R. A. ODUM, TOLEDO ZOO

At the Plenary Session that opened the meeting, I drew attention to the special events sponsored by SSAR to be held during the week, in particular those designed for students. I reminded students about our third-annual Student Social (co-sponsored with HL), which is designed specifically for students to meet senior herpetologists. (Nearly 200 people attended, by the way.) James Hanken, director of the Museum of Comparative Zoology at Harvard University and Immediate Past-President of ASIH, delivered a sobering address about the prospects for biological research funding and the future of biological societies. He said that the national trend over the past decade is that the memberships of the smaller societies have gone down as much as 40%, but he noted that SSAR was an exception. Over the last decade, SSAR has increased 20% in size. As of the end of 2010, it is now the largest of the JMIH societies. As I mentioned in my last message, these promising numbers should not allow complacency, rather they should act as an impetus to continue to improve and expand SSAR programs and benefits for members.

BOARD OF DIRECTORS MEETING: Although the society is in good financial condition, our plans exceed our current income levels. The board took a bold step to make changes in its two journals last March, but to sustain full color imagery in *HR* and more color in *JH* (as well as other improvements to these serials), to remake and expand our website, to further enrich our meetings, and especially to provide more enhancements for students, we simply need to increase our revenue. Postage costs, both domestic and international, have dramatically increased. (The postage alone for overseas members now exceeds $31 per year!) We have not had a dues increase for several years. Accordingly, the board decided to adjust fees and these will be noted in the renewal reminder that will be sent to you this fall. I think members will find the increases to be modest and we anticipate that our improved programs and publications will be well worth the minor change. There will be a small increase of $5 for student and zoo members, but a *decrease* of $20 for seniors over 70 years of age. As I anticipated in my March letter to you, the board voted to establish a new category of membership, Associate Member, a non-voting category that will receive *HR* only. Given the great reception of the newly formatted *HR*, we anticipate that this will be a popular membership option.

Even at the new dues levels (which will be at or below those for our sister societies), we think that SSAR is still the best bargain in herpetology, worldwide. All of our regular, senior, student, and zoo members receive two quarterly journals and are offered discounts on SSAR books and other publications. Students get substantially reduced fees at our meetings and have the opportunity to win research awards, travel awards, and prizes for their research at our meetings. Equally important, our members support everything that SSAR does to promote herpetology in terms of research, conservation, and education. Nonetheless, we believe that SSAR's potential is still only partly realized. With the adjusted dues schedule and an increase in membership due to the many improvements, SSAR can do far more for the herpetological community, internationally, than it does today.

Incidentally, the Board of Directors' meetings, as for all SSAR-sponsored meetings, are always open to our members. We want our deliberations to be transparent and, indeed, we want feedback. And for those who wish to actively participate, we can find ways in which you can help to advance the goals of the society.

LONG RANGE PLANNING COMMITTEE MEETING: Because the LRPC is leading the changes in SSAR, an open meeting was held to attract members to provide feedback to the committee. About 35 members attended and it was especially gratifying to see so many students present. The LRPC previewed current issues under consideration: meeting venues, web page, electronic-only memberships, and international reach. Historically, our meetings have been SSAR-only or SSAR/HL joint meetings on university campuses, but in recent years now they have been JMIH events in downtown conference centers. LRPC will discuss the possibility of alternating herp-only, campus venues with JMIH events at conference centers, and also the feasibility of sponsoring more meetings at non-USA sites. (SSAR has met in Mexico twice and in Brazil, Canada, and the UK once each.) There was an extensive discussion of SSAR's current website and its limitations. Simply put, our website needs to provide a portal to all-things-herpetological, in order to serve both our membership and the general public. We are not there yet, and the LRPC will be considering a complete makeover of the site, making it more interactive and greatly expanding its function. The dues increase is partly in anticipation of the major changes we wish to make in our web page that will require professional development and maintenance. The assembled group, especially the younger members, was strongly in favor of getting their issues of *JH* and *HR* electronically. So, this will be a priority for SSAR to make this happen soon. Note that currently SSAR members can access entire electronic issues of *HR* via the ZenScientist website. Finally, there was discussion of SSAR's international status and how the society can be made more relevant and useful to overseas herpetologists. There was excellent feedback from the audience on all of these points and some good ideas, too!

BUSINESS MEETING: I was very pleased to welcome nearly 200 members to the Business Meeting. Numerous reports were delivered by the relevant society officers and editors. Our

Treasurer, Kirsten Nicholson, noted that our budget has dramatically increased from $263,500 in 2011 to $394,800 for 2012, although the latter figure is inflated by about $75,000 because of a major, one-time publication project (see below). Many student prizes and awards were announced and these will be detailed in the full report of our annual meeting in the December issue of *HR*. A new category of prizes was instituted this year for Best Student Poster, so that oral and poster presentations can now be accorded equal importance. (We expect to announce a major new endowment to support the poster awards in the near future.) It was announced that SSAR will be making significant contributions to next year's meeting at the 7th World Congress of Herpetology, to be held on the spectacular Vancouver campus of the University of British Columbia in August. These include a congress poster and several giveaway publications. SSAR will also run the auction, with all proceeds going to the congress. SSAR has long had a close relationship with the WCH and has provided gratis publications at each congress. (The WCH was founded at SSAR's silver anniversary meeting in 1982.)

It was officially announced at the Business Meeting that SSAR will be issuing a special set of volumes as its salute to next year's world congress, the first to be held in North America. SSAR will publish a facsimile reprint of Duméril and Bibron's classic work, "Erpétologie Générale" (1834–1854), one of the largest single works ever issued in herpetology and the greatest one in the French language. This consists of 10 volumes and an atlas, with over 7,000 pages of text and 120 color plates. Funding is now assured thanks to the generous support of Ronald Javitch, our long-time member and benefactor in Montreal. Duméril and Bibron's volumes still are a key work for systematists today, and are especially needed in developing countries. An original copy today with colored plates costs $20,000, if you can find it at all, but SSAR is hoping to price this set at no more than $300. Full details will appear in *HR* next March.

OTHER EVENTS IN MINNEAPOLIS: We hosted the best herpetological party of the decade, in the form of the Ernie Liner Mardi Gras auction (to develop an endowment to support, in Ernie's words, "up-and-coming herpetologists"). The event was well attended and a lot of fun as bidders fueled themselves with Hurricane beverages and competed for Mardi Gras beads. The auction items were all drawn from Ernie's vast collection of books, art, and whimsical herp-related toys and nicknacks. On a more serious note Jaime Garcia-Moreno and Phil Bishop of the IUCN Amphibian Survival Alliance were in attendance to network on behalf of that newly launched organization. The SSAR Board approved a resolution formally endorsing the organization.

Finally, I would like to highlight two motions that the SSAR Board approved during our meeting, because I feel that these two gestures exemplify the inclusive attitude of our society. From now on, all communications regarding students in our programs will be phrased "undergraduate and graduate students" in order to make explicit that we encourage participation from students at all stages of their career. One step further toward that notion is the new Board-approved program to offer a free 1-day registration fee for pre-baccalaureate (i.e., K–12) student (and an accompanying guardian) to attend our annual meeting. I can only imagine the thrill I would have felt had I had the opportunity to attend an SSAR meeting when I was in high school! These two gestures, approved by the Board, mean a lot to me as it helps me communicate that everyone is welcome at SSAR. We want your input and we want you to join and contribute to our programs and broad family of publications as we expand the society's programs and redirect them into areas relevant to where our field will be going during the 21st century.

Joseph R. Mendelson III, President

ABOUT OUR COVER: *OPHIOMORUS NUCHALIS*

The "snake skinks" of the genus *Ophiomorus* are characterized by an elongated body and reduced appendages, fully absent in some species. The ten described species collectively range from Greece through southwest Asia to northwestern India. Little is known of the ecology of this group, though several species occur in windblown dune sand habitats. These sand specialist species display a suite of adaptations for life in the dunes: wedge-shaped snouts, lack of external ear openings, elongate morphology, extremely smooth imbricate scales, prominent ventrolateral edge, and small grooves into which forelimbs are folded during subsurface locomotion. Snake skinks are nocturnal, emerging onto the surface after sunset to feed. Dune-dwelling species may be found by following their tracks.

The Plateau Snake Skink (*Ophiomorus nuchalis*) is a rare lizard, first described by Nilson and Andren based on two specimens from the Kavir Desert, in north-central Iran (1978. Copeia 1978:559–564). The type locality is a localized permanent spring in an otherwise hot, dry environment, and the population was presumed to be small. The species remained unrecorded until 1999–2000, when two additional animals were found at the type locality. In 2009, a second population was discovered, about 120 km distant from the first site and near the northern boundary of the Kavir Protected Region (Mozaffari et al. 2011. Russian Journal of Herpetology 18[1]:36–38), associated with loose soil under small desert shrubs. The recent discovery in a habitat that is common in desert regions of Iran's Central Plateau suggests that *O. nuchalis* is probably more widely distributed than previously thought.

Our cover image, depicting an adult male *Ophiomorus nuchalis*, was recorded by Iranian herpetologist **Omid Mozaffari**, in May 2010 near the village of Mobarakieh, Tehran Province, using a Fujifilm FinePix S9600 digital camera with fill flash. Mozaffari is one of the founding members of the Pars Herpetologists Institute (www.pars-herp.org), Iran's first herpetological society, begun in 2006. His field research is focused toward completing the Atlas of Reptiles of Iran project.

Dean E. Metter Memorial Award for 2011

There were 27 proposals submitted this year for the Dean E. Metter Memorial Award. The proposals all had considerable merit; however, two stood out from the others and President Mendelson granted permission to make two awards.

The first award winner is Brandon Fessler, a student in the Department of Biological Sciences at Central Washington University in Ellensburg, Washington. He is an M.S. student who is studying the seasonal behavior, habitat use, and spatial ecology of *Dicamptodon tenebrosus*. His graduate committee is chaired by Jason Irwin; other committee members are Daniel Beck and Marc Hayes.

The second awardee is Jessica Wood of the Division of Biological Sciences at the University of Missouri–Columbia. Jessica is a student of Carl Gerhardt's and her proposal details a segment of her PhD dissertation and is entitled, "Behavioral Analysis of Signal Plasticity and Mate Recognition in *Hyla femoralis*."

The Metter Award Committee extends its sincere thanks to all the students who submitted proposals this year. We wish all of you the best and look forward to reading about the results of your graduate work in the herpetological literature.

Kennedy Student Award

The Kennedy Student Award Committee (Bill Lutterschmidt, Mark Paulissen, Terry Schwaner, Lynnette Sievert, Chair) has completed its work for Volume 44 of the *Journal of Herpetology*. The Committee has selected "New Loam-Swimming Skink, Genus *Brachymeles* (Reptilia: Squamata: Scincidae) from Luzon and Catanduanes Islands, Philippines" by Cameron D. Siler, co-authored with Arvin C. Diesmos and Rafe M. Brown (vol. 44:49–60). The Kennedy Award carries with it a cash prize of US $200 or the winner's selection of any SSAR publications valued at twice that amount.

The Committee invites all student members of the Society to submit their work to the *Journal*, and encourages regular members who supervise the work of students to draw this award to the attention of those students.

SSAR Grants-in-Herpetology Program Guidelines for Proposal Submission

NOTE: In June 1999, the SSAR Board decided that past award recipients are not eligible for additional GIH awards.

Proposals are now being accepted for the **2012** SSAR Grants-in-Herpetology Program. This program is intended to provide financial support for deserving individuals or organizations involved in herpetological research, education, or conservation. Grant proposals will be considered in the following categories:

1. **CONSERVATION OF AMPHIBIANS AND/OR REPTILES.** Proposals should address research (particularly conservation biology) on species endangered or threatened at the state, national, or international level, or address research on potentially threatened habitats or species, or on introduced injurious species. Proposals must be accompanied by a letter of support from another member of the SSAR or a student's major advisor or committee chairperson.
2. **FIELD RESEARCH.** Proposals may address needs for field station fees or equipment and materials in field oriented projects, or the field work portions of broader studies. This might include in-situ behavioral studies, ecological, life history, or sexual selection studies. Survey work by individuals or regional societies may be submitted here or in TRAVEL below depending on how the funds are to be used. Proposals must be from individuals only and be accompanied by a letter of support from another member of the SSAR, the president of the sponsoring regional society (if applicable), or a student's major advisor or committee chairperson.
3. **LABORATORY RESEARCH.** Proposals may address needs for equipment or materials in laboratory projects or laboratory portions of broader projects. This might include studies in behavior, biochemistry, molecular biology, biomechanics, or physiology. Proposals must be from individuals only and be accompanied by a letter of support from another member of the SSAR or a student's major advisor or committee chairperson.
4. **HERPETOLOGICAL EDUCATION.** Proposals may address an educational project or start up support for an educational program in a zoo, museum, park, nature center, regional herpetological society, etc. The project must focus on a herpetological topic. Proposals must be from individuals only and be accompanied by a letter of support from the herpetological curator, the director of the facility, or the regional society president. Applicants need not be students or a SSAR member.
5. **TRAVEL.** Proposals may address support for travel to field study sites near or far, or to utilize distant collections or facilities. If funding is sought to get from one place to another, proposals should be submitted in the TRAVEL category. Proposals normally submitted in the CONSERVATION or FIELD RESEARCH categories should be submitted here if travel funding is being sought. Proposals must be accompanied by a letter of support from another member of the SSAR or a student's major advisor or committee chairperson, or the regional society president.
6. **INTERNATIONAL.** Proposals may address needs in any of the above five categories. The applicant must be a student, but not necessarily a SSAR member. Preference will be given to students with limited access to research funds and in countries where herpetological research has historically been under-funded.

In keeping with the Society's goal of encouraging participation by the broadest possible community, preference may be given to individuals who might not have access to other funding sources. All applicants must be students AND members of the SSAR with the following exceptions: 1) those applying for support of regional herpetological society projects need not be SSAR members; 2) those applying for the International category must be students but need not be SSAR members; 3) those applying for the Herpetological Education category need not be a student or a SSAR member.

Membership dues must be paid (to SSAR Treasurer) no later than 15 December 2011 for proposals to be considered. Applicants are limited to submission of one proposal in one category per year. Past recipients of an SSAR GIH award in any category are not eligible for future awards. Applicants must designate to which of the six categories their proposal is submitted (although the committee reserves the right to reassign proposals to categories). If proposals in any of the categories are not forthcoming, or judged not to be of sufficient quality, the funds in those categories may be transferred to other categories. Each proposal must include the following:

(A) TITLE PAGE giving the title of the project, the name, mailing address, office and home telephone numbers and, if possible, fax number and e-mail address of the applicant. The title page should also include the following numerated items completed in this format on the bottom left corner of the Title Page:

1) Category:
2) Word count:
3) Student status (give school):
4) SSAR membership since:
5) SSAR budget portion (amount and brief description):
6) a statement indicating that applicants "will comply with all applicable permit regulations, and adhere to all appropriate animal care guidelines in the course of conducting funded projects.";

(B) BACKGROUND AND OBJECTIVES of the proposed project.

(C) METHODS of carrying out the project.

(D) COMPLETE PROJECT BUDGET (regardless of whether the SSAR grant will entirely cover expenses). Include an explicit explanation of how an SSAR award of $500 would be applied toward the objectives of the project (here as well as on Title Page), and provide a listing of all current and pending support for the project.

(E) BRIEF RESUMÉ/CURRICULUM VITAE of the applicant or project coordinator.

(F) LETTER OF SUPPORT.

The proposal must be typed, double spaced, and must not exceed 1,200 words, excluding title page, literature cited, curriculum vitae (resume), and budget. All proposals are to be submitted electronically to kapferj@uww.edu as a single PDF file named "lastname-category.pdf" no later than 15 December 2011 to be considered (letter of support may be included with the proposal or sent separately). (Exceptions to electronic submission and file format may be allowed for special cases with prior approval by SSAR-GIH Chair). Failure to meet these guidelines may result in elimination of a proposal from consideration. The awards will be announced in April/May 2012.

These guidelines are also available online at: http://www.ssarherps.org/pages/GIH.php

Successful applicants are encouraged to submit the results of their research for publication in the *Journal of Herpetology* or *Herpetological Review*, or to present their findings at the annual meeting of the SSAR. Submit proposals or questions regarding application procedures to:

Joshua M. Kapfer
Chair, SSAR Grants in Herpetology
Department of Biological Sciences
University of Wisconsin-Whitewater
Whitewater, Wisconsin 53190, USA
e-mail: kapferj@uww.edu

Grants In Herpetology Donor Information

Financial contributions by SSAR members, institutions, and other benefactors support this program significantly, and can increase the number and/or size of awards. Your tax-deductible contribution to this program will directly benefit meritorious research and education in herpetology. Contact the Treasurer of SSAR for additional information about contributing to the Grants-in-Herpetology Program. If you are employed by an organization that will match donations made to nonprofit organizations, please notify your employer that you have made a donation to the Grants-in-Herpetology Program.

NEWSNOTES

Amphibian Survival Alliance

The Amphibian Survival Alliance (ASA) is a new initiative established by the International Union for the Conservation of Nature (IUCN) to coordinate and magnify conservation efforts to stop and reverse the ongoing crisis of global amphibian declines.

In 2009, a coalition of organizations agreed to set up an interinstitutional Amphibian Survival Alliance to oversee the implementation of the Amphibian Conservation Action Plan (ACAP) that was drafted in 2005—focusing initially on habitat destruction and climate change, the fungal disease chytridiomycosis, and over-harvesting. This is expected to promote synergies and facilitate communications both within the amphibian community and with all the relevant stakeholders. IUCN has recently appointed Dr. Jaime García-Moreno and Dr. Phil Bishop to serve, respectively, as Executive Director and Chief Scientist of the Amphibian Survival Alliance. They will oversee the formation and coordination of a global network of partner organizations to facilitate implementation of research, conservation, and assessment programs as outlined in the ACAP.

The ASA is supported by and will be working in collaboration with organizations such as Conservation International, the Zoological Society of London, the Detroit Zoological Society, the North of England Zoological Society, Wildlife Conservation Society, and Frankfurt Zoo, as well as related initiatives such as the Amphibian Ark and the Amphibian Specialists Group. Jaime García-Moreno will work from his office at EAZA (European Association of Zoos and Aquaria) and is based in the Netherlands, closely collaborating with the Zoological Society of London and other partners of the Alliance. Phil Bishop will remain based at the University of Otago in Dunedin, New Zealand. They may be contacted at: Jaime.GarciaMoreno@iucn.org and Phil.Bishop@iucn.org.

Amphibian Declines Teaching Module Available from Free Download

Now available, via the Network of Conservation Educators & Practitioners (NCEP; a program of The American Museum of Natural History), is an outreach teaching module reviewing all aspects of the global crisis of amphibian declines and extinctions. Module includes a thoroughly annotated and illustrated PowerPoint presentation, an overview synthesis monograph with extensive literature citations, as well as proposed in-class teaching exercises and solutions. The module is aimed toward university-level students (e.g., Conservation Biology, Herpetology courses) but it is open-format so it can be edited and customized to any particular need or audience.

Link for free download: http://research.amnh.org/biodiversity/ncep

Mendelson, J. R., III, and R. Donnelly. 2011. The Crisis of Global Amphibian Declines: Causes, Consequences, and Solutions. Network for Conservation Educators and Practitioners, American Museum of Natural History. CD-ROM. System requirements: IBM PC or Mac compatible. Windows 98 or higher. Also available electronically at: (PowerPoint Teaching Tutorial, plus associated pedagogical materials). 97+ pp.

The authors also are actively seeking K–12 and other educators to collaborate to prepare versions of this module appropriate for non-university students and public audiences. For more information, or copies of these materials, please contact Joe Mendelson: jmendelson@zooatlanta.org

New Blog on Lizards of the Genus *Anolis*

Anole Annals (http://anoleannals.wordpress.com/) is a new blog focused on all things *Anolis*. It aspires to be the clearinghouse for information, observations, and announcements of all matters involving anoles, including reports on new papers, description of natural history observations, information on ongoing research projects and interests, anecdotes, photographs, and news on anoles in commerce, history, and philosophy. Posts are encouraged from all interested in matters anoline.

The Herpetologists' League EE Williams Research Grant

The Herpetologists' League is pleased to announce competitive grants for graduate student research for 2012. These awards are named in honor of the late Ernest E. Williams, the first Distinguished Herpetologist of The Herpetologists' League. This is a cash award of US $1,000 in each of five categories (Behavior, Conservation, Ecology, Physiology, Morphology/Systematics), with an entry deadline of 15 December 2011. Please consult the HL web site for application form, complete rules and details: www.herpetologistsleague.org/dox/eewilliamsgrant.pdf

The J. Larry Landers Student Research Award

The J. Larry Landers Student Research Award is a Gopher Tortoise Council competitive grant program for undergraduate and graduate college students. Proposals can address research concerning Gopher Tortoise (*Gopherus polyphemus*) biology or any other relevant aspect of upland habitat conservation and management. The amount of the award is variable, but has averaged US $1,000 over the last few years.

The proposal should be limited to four pages in length and should include a description of the project, a concise budget, and a brief resumé of the student.

This is an excellent opportunity for undergraduate and graduate students to access funding for their projects.

The deadline for grant proposals each year is 15 September. Submissions should be sent to:

Dr. Bob Herrington
Department of Biology
Georgia Southwestern State University
Americus, Georgia 31709, USA
Tel. 229/931-2331; e-mail: bherring@gsw.edu

MEETINGS

Meetings Calendar

Meeting announcement information should be sent directly to the Editor (HerpReview@gmail.com) well in advance of the event.

25–29 September 2011—Joint 16th SEH European Congress of Herpetology & 47th DGHT Deutscher Herpetologentag (annual meeting of the German Society for Herpetology and Herpetoculture, scientific part), Luxembourg. Information: http://www.symposium.lu/herpetology

30 September–2 October 2011—47th DGHT-Nachzuchttagung (annual meeting of the German Society for Herpetology and Herpetoculture, herpetocultural part), Trier, Germany.

3–7 January 2012—Symposium: New Frontiers from Marine Snakes to Marine Ecosystems. Society for Integrative and Comparative Biology annual meeting, Charleston, South Carolina, USA. Information: http://www.sicb.org/meetings/2012/symposia/marine.php

12–13 January 2012—California-Nevada Amphibian Population Task Force Meeting, Placerville, California, USA. Information: bradford.david@epa.gov

8–14 August 2012—World Congress of Herpetology 7, Vancouver, British Columbia, Canada (together with SSAR, HL, ASIH). Information: http://www.worldcongressofherpetology.org/

2–7 September 2012—4th International Zoological Congress (IZC), Mount Carmel Campus, University of Haifa, Haifa, Israel. To receive the first and subsequent meeting announcements, contact the organizers at: izc2012@sci.haifa.ac.il.

CURRENT RESEARCH

The purpose of Current Research is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, Joshua Hale or Ben Lowe; e-mail addresses may be found on the inside front cover.

A listing of current contents of various herpetological journals and other publications is available online. Go to: http://www.herplit.com and click on "Current Herpetological Contents."

Chytrid Assay for Formalin-fixed Specimens and Elucidation of an Amphibian Extinction Wave

The fungus *Batrachochytrium dendrobatidis* (*Bd*) is a pathogen of amphibians and both histological and polymerase chain reaction (PCR) methods have been developed for establishing its presence. While the utility of using PCR assays on formalin-fixed museum specimens has long been noted, previous attempts have failed to devise a reliable method, leaving only time-consuming histological assays. The authors of this study describe a method for PCR assaying formalin-fixed specimens for *Bd* infection. This method entails thoroughly swabbing the skin of the specimen, extracting DNA from swabs using standard protocols, and real-time PCR amplification/quantification of a 146 base pair segment of DNA (mtDNA: ITS-1). To determine effectiveness of this method, animals which had previously been assayed via the histological method were subjected to the PCR assay. This revealed that two or more PCR assays per specimen results in the same detection success as one histological assay. The authors attribute the success of this method to the short length of the target DNA segment, multiple tests per animal (resulting in a test with acceptable error rates), and targeting of the skin (where *Bd* is expected to be most highly concentrated). As a case study to demonstrate the utility of these methods, the authors performed PCR-based *Bd* assays on a number of formalin-fixed specimens from Mexico, Guatemala, and Costa Rica. Cumulatively, these results strongly support *Bd* as a causal agent in the recent declines and extinctions of neotropical amphibians, with precipitous frog and salamander declines immediately following the detected emergence of the pathogen. Together with previous studies, these results suggest a wave of *Bd* originating in southern Mexico in the early 1970s, spreading south across Guatemala in the 1980s, reaching Monteverde, Costa Rica, in 1987, and central Panama in 2004. To further investigate the susceptibility of neotropical amphibians to *Bd*, individuals of two bolitoglossine salamander species and a hylid treefrog species were exposed to *Bd* in the laboratory (all frogs tested positive for chytrid at time of collection; some salamanders were left uninfected to serve as controls) and their condition was monitored for seven weeks. During the experiment, all infected salamanders rapidly increased in *Bd* infection and died; all infected frogs maintained infection at low levels and did not exhibit disease symptoms. These studies indicate the susceptibility of species to *Bd* is unpredictable and that species-specific laboratory-based experiments should be performed when possible.

Cheng, T. L., S. M. Rovito, D. B. Wake, and V. T. Vredenburg. 2011. Coincident mass extirpation of neotropical amphibians with the emergence of the infectious fungal pathogen *Batrachochytrium dendrobatidis*. Proceedings of the National Academy of Sciences (*in press*) doi:10.1073/pnas.1105538108.

Patterns of Detectability and Site Occupancy among American Aquatic Snakes

Determining the detectability of species is important when trying to interpret presence-absence data. The authors of this study investigated the relationships between detectability, fraction of sites occupied, and environmental variables in seven aquatic snake species. Capture-recapture data from repeated efforts using minnow traps was collected across twenty isolated wetlands in the Savannah River watershed of South Carolina, USA. Additionally, prey density (fish, crayfish, and aquatic salamander), distance from river, and water permanence were quantified and subjected to a principal components analysis. Subsequently, the modeling program PRESENCE was used to model detectability and number of sites occupied, allowing one to vary with one or both of the first two principal components while holding the other constant, or allowing both detectability and sites occupied to vary with the principal components. The authors discovered a wide range of detection probabilities and site occupancy fractions among the snake species, in harmony with studies of terrestrial snakes. Furthermore, many instances of strong correlation between detectability, site occupancy, and environmental variables were detected. For instance, the detectability for one widespread and generally detectable species, *Nerodia fasciata*, was positively correlated with crayfish abundance and negatively correlated with water permanence and fish and neotenic salamander abundance (principal component one; also correlated with population density). However, another widespread species, *Agkistrodon piscivorus*, exhibited the lowest detectability; the authors attributed this to the species' reluctance to enter minnow traps. These findings demonstrate the variable and generally low detectability of snake species and the importance of taking into account the potential correlates of detectability when modeling site occupation.

Many Potential *Bd* Mitigation Methods on the Horizon

Much research of late has been directed toward stemming the tide of amphibian declines and extinctions due to the chytrid fungus, *Batrachochytrium dendrobatidis* (*Bd*). In an attempt to synthesize this body of work, the authors of this review paper tackle the variety of methods currently used to control *Bd*-triggered declines in amphibians. They demonstrate that most conservation strategies can be divided into three categories: large-scale prevention of the spread of *Bd*, establishment of captive "insurance" colonies, and *in situ* treatments aimed at preventing or limiting *Bd* infection. The authors then briefly discuss a long list of potential *Bd*-fighting methods currently being explored. These include modifying habitats to be less hospitable to *Bd*, captive breeding of *Bd*-resistant lines for reintroduction, and the protection of "climatic refugia," where *Bd*-susceptible species persist with or without *Bd* present. While generally optimistic about the potential of proposed *Bd*-mitigation strategies, the authors emphasize that amphibian density reduction measures (via culling) likely will have negative consequences. They urge people planning conservation efforts to prepare to take more active measures in combating *Bd*. Additionally, fundamentally different methods (i.e., habitat-based, medical) may need to be attempted before a remedy is found for any given situation. They conclude with a list of questions which if addressed, could prove indispensable to the global efforts to combat the *Bd* pandemic.

Parthenogenic Lizard Lineage Initiated in Laboratory

It is well understood that across evolutionary time, parthenogenic lineages of North American whiptail lizards (Teidae: *Aspidoscelis*) have repeatedly formed as the consequence of hybridization. However, this phenomenon has not been replicated in the laboratory and this failure has led some to conclude that the vast majority of hybridization events lead only to hybrid, sexual individuals, and that parthenogenic lineages have effectively lost the ability to reproduce sexually. The authors of this paper report the first captive establishment of parthenogenic lizard lineages. Males of a sexual, diploid species (*A. inornata*) were paired with females of a parthenogenic, triploid species (*A. exsanguis*). These are not the parental species of any described parthenogenic species. Six eggs (the product of a single parental pair) were laid and resulted in the hatching of two males and four females. Quantification of nuclear DNA via flow cytometry revealed the offspring to be tetraploid and DNA microsatellite data indicated that all progeny exhibited genetic contributions from both parental species. These four females have resulted in 25 second-generation and 22 third-generation lizards, demonstrated via microsatellite analysis to be tetraploid clones. These findings follow studies in fish and amphibians, where naturally-occurring parthenogenic species have been recreated in the laboratory. However, asexual reproduction in those systems requires sperm contribution (but not necessarily DNA) from a sympatric, sexual male. The authors close with a discussion of the taxonomic implications of creating a parthenogenic tetraploid *Aspidoscelis* lineage in the laboratory and urge people working in the area of sympatry of these species to look for lizards matching the phenotype of the laboratory-generated lineage.

Garter Snakes Direct Blood Flow Depending on Temperature

Ability to control blood flow to various regions of the body is thought to be an important thermal management tool across the vertebrate spectrum. However, this ability has not been definitively demonstrated in snakes. The authors of this paper aimed to investigate this phenomenon using Common Gartersnakes (Natricinae: *Thamnophis sirtalis*) surgically outfitted for the aortic administration of blood plasma proteins labeled with a radioactive isotope (^{99m}Tc-MAA). Snakes were either cooled to ~7°C or heated to ~30°C, injected with ^{99m}Tc-MAA, and photographed using a gamma camera. Image analysis software was used to quantify the blood flow to the head and tail. These analyses demonstrated that common garter snakes do indeed direct blood toward their heads and away from their tails when subjected to cold temperatures. Furthermore, these snakes are capable of performing the opposite task when exposed to high temperatures. The authors propose that the non-essential nature of their post-cloacal anatomy afford these snakes the opportunity to preserve heat by pulling blood cranially. Alternatively, under hot conditions snakes can utilize the high surface-to-volume ratio of the tail to cool down as well as prevent overheating of the sensitive head. The authors encourage others to perform these experiments on representatives of other snake lineages and caution that these findings may not extend to snakes with tails of demonstrated function (such as marine snakes, arboreal snakes, and rattlesnakes).

Fox Snake mtDNA Discordant with Current Taxonomy

The American fox snakes (Colubridae: *Pantherophis vulpinus* and *P. gloydi*) have had a tumultuous taxonomic history, first being treated as monotypic conspecifics, subspecies, and most recently distinct species (without universal acceptance). Despite being ecologically divergent and geographically disjunct populations, morphological evidence for considering them separate species is tenuous and molecular data have been lacking. To shed light on this system, the authors of this paper accumulated mtDNA (cytochrome *b*) sequences and morphological data from across the distribution of this group. Phylogenetic analyses revealed mtDNA haplotype distribution discordant with described species, with populations west of the distributional break exhibiting eastern haplotypes. Instead, the mtDNA clades largely corresponded to the east and west sides of the Mississippi River; this geographic feature is increasingly being recognized as an important barrier to gene flow for recently-diverged lineages. However, there appear to have been recent trans-river colonizations, blurring the line between the two mtDNA clades. Dorsal blotch count (the character originally used to define these species) was found to show the same difference at the Mississippi River as it does across the distributional break. A molecular clock analysis places the divergence of the two mtDNA clades within the Pleistocene; this is in accordance with the fact that all of the fox snake's current distribution was under ice at some point during the Pleistocene. The authors conclude with possible explanations for these incongruent lines of evidence, suggest a reassessment of the distributions of these species, and discuss accompanying nomenclatural repercussions.

Ancient Divergences at Stream Drainage Divides in Terrestrial Salamander

Researchers investigating the origins of biological diversity have long understood the effect river drainages have on freshwater organisms. However, water features can also serve to prevent gene flow in terrestrial organisms. The authors of this paper sought to identify the phylogeographic structure and its potential hydrological underpinnings in a direct-developing salamander species, *Plethodon caddoensis* (Plethodontidae), which is endemic to the sky islands of America's Interior Highlands. mtDNA sequence data from across the distribution of this species and its two close relatives, *P. ouachitae* and *P. fourchensis*, were assembled and subjected to phylogenetic analyses (including a time-calibrated analysis). DNA sequences were also analyzed in partial Mantel tests to probe for phylogeographic structuring due to geographic distance, watersheds, and their constituent stream drainages. Importantly, as these variables are correlated, these analyses were conducted using the molecular data and each variable, while controlling for the other variables. Finally, ecological niche model analyses were performed using the locality data. These analyses were aimed at identifying the ecological variables that may be important in defining the distribution of this species. Furthermore, results from this analysis and analyses conducted on *P. ouachitae* and *P. fourchensis* were included in a Principal Components Analysis (PCA) intended to discover how *P. caddoensis* differs ecologically from its close relatives. The phylogenetic analyses revealed *P. caddoensis* consists of four deeply divergent lineages, each comparable in age to the species *P. ouachitae* and *P. fourchensis*. These primary clades diverged in the Middle Miocene, a period marked by aridification and a general succession from deciduous forest to grasslands. Overall, the molecular data show strong correlations with distance, watershed, and stream drainage. However, the correlation between molecular and geographic distance disappears when only comparisons between mitochondrial clades are examined; the authors interpret this to mean distance has not been a contributor to major lineage diversification in this system. Nevertheless, the lineages do meet at divides between drainage basins, suggesting the arid divides have served as barriers to dispersal while the streams within the drainages have not. The environmental niche modeling analysis found surface geology and wet season precipitation level to be the most important environmental variables for this species. Finally, the PCA revealed *P. caddoensis* to occupy a niche different from those of its close relatives and to be instead adapted to a warmer, wetter climate. This study exposes more fine-scale, cryptic diversity in lungless salamanders and sheds light on the sources of this diversity.

Shepard, D. B. and F. T. Burbrink. 2011. Local-scale environmental variation generates highly divergent lineages associated with stream drainages in a terrestrial salamander, *Plethodon caddoensis*. Molecular Phylogenetics and Evolution 59:399–411.

Continental Scale Climate Patterns Affect Lizard Phenology

One important tool for understanding the potential demographic effects of climate change is mechanistic modeling, where a species' physiological requirements are determined (often under laboratory conditions) and are used to establish when and under what biotic and environmental conditions the species can be in a positive energy balance or engage in certain behaviors. The authors of this study created a phenology model for Side-blotched Lizards (Phrynosomatidae: *Uta stansburiana*), field-tested their predictions for seasonal activity and reproductive timing in the deserts of eastern Oregon, USA, and examined long-term phenological trends in this population. As a metric of cumulative thermal energy, the authors used degree-days—the sum of daily temperature average minus the minimum body temperature needed for activity. Previous work established that these lizards require air temperatures at or above 10°C to

be active and have a preferred body temperature of 35°C, which the lizards can achieve through thermoregulation at air temperatures in excess of 15°C. Furthermore, in laboratory common garden experiments, the authors found that these lizards require a minimum of 550 degree-days for egg yolk formation. These values adequately mirrored estimates obtained over six years of field studies. Then, using these phenological parameter values and atmospheric temperature data from the site, they calculated beginning, end, and length of growing season and timing of reproduction for the past 70 years and performed linear regressions on the predictions. These estimated values were then included in a multiple regression analysis, where they were they were evaluated for correlations with two continental-scale climate phenomena: the El Niño-Southern Oscillation (ENSO) and Pacific Decadal Oscillation (PDO). As any given year's ENSO or PDO status is not independent of its thermal and phenological status, the authors were particularly focused on the fit of models not including year but instead previous and next year's ENSO and PDO status. The linear analysis of the 70 years of modeled phenological phenomena showed that growing seasons have shortened recently, both beginning later and ending sooner. Although this may seem contrary to general climate change trends, other climate studies have shown that the Great Basin Desert has cooled while surrounding regions have warmed. They also showed that large variations in annual phenology make any given year's pattern largely independent of climate fluctuations occurring at the scale of centuries or longer. The multiple regression analyses revealed shorter and earlier ending growing seasons to be correlated with the previous year exhibiting PDO conditions. Conversely, early timing of reproduction was found to be strongly correlated with ENSO conditions the previous year. Considering these two independent climate variables affect different phenological aspects of this lizard's life history, the authors posit that predicting future demographic changes in these types of systems may be difficult.

Bd Correlated with Amount of Surrounding Habitat Loss

With the fungal pathogen *Batrachochytrium dendrobatidis* (*Bd*) ravaging amphibian populations across the globe, understanding the correlates of infection is of great importance to conservation efforts. Many *Bd*-implicated amphibian extinction events have occurred at high elevations, which has been considered a consequence of *Bd*'s affinity for cool, moist habitats. The effect of habitat loss on *Bd* prevalence has not been determined, however, disturbed habitats generally are associated with increased disease prevalence. To elucidate potential correlates of *Bd* infection, the authors of this study collected data on frogs from three regions known to harbor *Bd*: *Craugastor fitzingeri* in Costa Rica, *Dendropsophus minutus* in Brazil's Atlantic Forest, and *Litoria lesueuri* in eastern Australia. Data were collected for habitat loss, frog species richness, elevation, latitude, as well as a large number of temperature and precipitation metrics. Additionally, using quantitative PCR, sites across these three regions were sampled for *Bd* prevalence (percent of animals infected) and intensity (zoospores per animal) (due to sample size restrictions, Costa Rica estimates limited to presence-absence); estimates of animal density were also determined where possible. These variables were then subjected to a series of regression analyses which explain (directly or indirectly) *Bd* presence, prevalence, and intensity. In all cases, habitat loss was found to be strongly correlated with *Bd*. Interestingly, this association was negative, with more *Bd*-infection in more pristine habitats. Additionally, anuran diversity was found to be positively associated with *Bd*. According to the authors, these findings suggest that the lack of diversity and relative aridity exhibited by isolated patches of frog habitat make for suboptimal *Bd* environments. Furthermore, the authors detected a strong interaction between elevation and habitat with regard to *Bd*, which they took to mean that the observation that high elevation frog communities have disproportionately suffered *Bd*-implicated declines is due in part to habitat loss being disproportionately a low-elevation phenomenon. The authors warn that this should not be viewed as a consolation, as habitat loss has even more dire consequences than *Bd*. As this study has shown, conservation biologists must be cognizant of all potential factors triggering declines, as well as their possible interactions.

Fish Implicated in Decline of Salamander Species

Although fish can directly impact salamanders through predation, fish can also inhibit salamander activity by initiating defensive behavior in the salamanders. The authors of this paper investigated the interactions between Long-toed Salamanders (*Ambystoma macrodactylum*) and a freshwater fish, the Lake Chub (Cyprinidae: *Couesius plumbeus*), in Alberta, Canada. Surveys were made of adult salamanders returning to the lake, larvae, and egg masses, and these figures were then compared with similar estimates made fifteen years earlier in an attempt to determine the salamander population size trajectory. In the laboratory, experiments were conducted to determine behavior and survivorship of salamander larvae in the presence of fish. Furthermore, although the salamanders are expected to engage in cannibalism, the frequency of this behavior in this system is not known, and therefore the authors also attempted to identify the correlates of this phenomenon. The population size estimates showed the salamander population to be in a steep decline. Indeed, in the two years of sampling, only a single larva was observed. The laboratory experiments revealed that larval salamander survivorship increased with size and when in the presence of fish, salamanders decreased their activity levels as

well as occupied areas away from the fish. Additionally, larger salamanders were more likely to engage in cannibalism. Interestingly, salamanders were not observed engaging in anti-predator behavior when in the presence of a potentially cannibalistic conspecific. The authors conclude that this salamander species may be negatively affected by the Lake Chub, both directly through predation and indirectly by initiating anti-predator behaviors, and that this fish may be the cause of population size decline in this system.

OBITUARIES

Herpetological Review, 2011, 42(3), 330–333.
© 2011 by Society for the Study of Amphibians and Reptiles

In Memoriam: Osvaldo Rodrigues da Cunha (1928–2011)

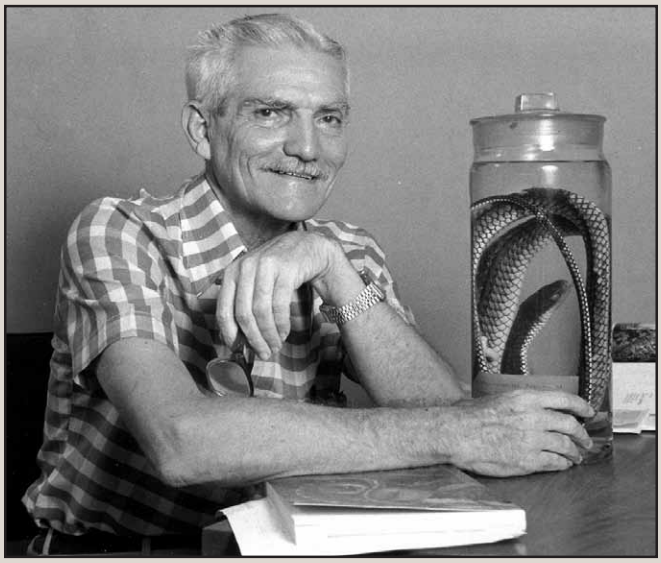

PHOTO BY JANDUARI SIMÕES, COLLECTION OSVALDO RODRIGUES DA CUNHA

Fig. 1. Osvaldo Rodrigues da Cunha in 1991, with a specimen of *Chironius carinatus* (Linnaeus, 1758) of the MPEG collection.

Osvaldo Rodrigues da Cunha, retired researcher of the Museu Paraense Emílio Goeldi (MPEG), founder of the sector of herpetology and of the herpetological collection of MPEG, tireless researcher of Amazonian reptiles and also of its scientific history, especially of the MPEG and persons connected to it, died on 11 March 2011 in Belém at the age of 82 years. The last three years he was plagued by weak health and loss of sight.

Osvaldo Rodrigues da Cunha was born on 6 April 1928, in Belém do Pará, Brazil, as the eldest son of the Portuguese couple Carlos Pereira da Cunha and Ana Cerqueira Rodrigues da Cunha, who had one more son and two daughters. Osvaldo Cunha attended primary school and gymnasium in Belém until 1946. He refused to follow university courses offered at that time because he considered them inadequate for the natural history studies that he wanted to do. His interest in natural history probably was instigated by frequent visits to the zoobotanical park of MPEG, close to his house. He preferred to prepare himself via practical work, initially in MPEG and later on in Museu Nacional (MN), in Rio de Janeiro, and Museu de Zoologia, in São Paulo (MZUSP), and by studying in the libraries of these institutions. With this in mind, he entered MPEG as a volunteer in the Zoology Department in 1945, where he started studying butterflies and beetles from the area around Belém. Between September 1949 and January 1951 he was a volunteer in the Zoology Department of the MN in Rio de Janeiro, where he also attended courses in Biology, Comparative Anatomy, Statistics applied to Biology, Practical Natural History, and General Biology. During this period in MN he met Antenor Leitão de Carvalho, who encouraged him to study reptiles. Finally, from September 1963 to December 1964 Cunha was a volunteer with Paulo Emílio Vanzolini, director of the Museu de Zoologia de São Paulo and trained as a herpetologist in the USA. In MZUSP he could participate in scientific projects, talks, meetings, and seminars. During this stay in São Paulo he also met Alphonse Richard Hoge, chief of the herpetological section of the Instituto Butantan, with whom he later on (1980) published a paper. During this initial phase, besides his studies in natural sciences, Osvaldo Cunha already showed his interest in the history of science, writing several articles on the subject for newspapers in Belém. It is also from this time on that he started his own library, which grew considerably until his retirement.

In MPEG, Osvaldo Cunha was appointed "Naturalist" on 17 December 1953 and Zoological Researcher in 1966, at that time already focusing on reptiles. Between 1955 and 1962, however, due to institutional problems, he worked in the Geology Department. Together with the geologist C. S. Ferreira he published during this period a number of papers on paleontology, but at the same time he continued his studies on reptiles. The first small paper on lizards, in 1958, dealt with a new occurrence (of *Bachia*) in Amazonia, but the second, from 1961, dealt with the species of lizards then known from Brazilian Amazonia. It is the first paper on a South American group of lizards that covers a large area. The study was based only on material from the MPEG collection, but this pioneering paper formed the basis for other more encompassing studies on lizards (e.g., Avila-Pires 1995, which also took into account material from the principal European and U.S. museums). These first papers on lizards were followed by six

more in this series, up to 1981. Number IV of this series (Cunha 1971) was the description of a new genus and species (*Amapasaurus tetradactylus*) from Amapá, based on two badly preserved specimens collected in 1960 and 1969. It was not until 2004 and 2006 that more specimens were collected in Amapá (Tumuc Humac expedition of Conservation International), and in 2008 the species was also found in northern Pará (see Avila-Pires et al. 2010 for a photo of this rare lizard).

In June 1965 Cunha established the Herpetological section of MPEG, with a collection of 650 specimens (a number of specimens before this period had gone to other institutions, either as donations or as loans that never returned). In 1965 Cunha started to train Francisco Paiva do Nascimento, who became his most important collaborator, in herpetological work. The results of this cooperation were very successful for the knowledge of the Amazonian reptile fauna, especially that of Pará, and for the herpetological collection of MPEG.

In order to undertake an inventory of the herpetofauna of Pará, Cunha and Nascimento developed a simple, but effective system to obtain specimens for the collection, by enlisting the help of rural people in a number of localities in eastern and southern Pará and western Maranhão (see maps in papers of Cunha and Nascimento about snakes from these areas). In each locality they trained one person to fix specimens that were collected by injecting formol 4% (one part formaldehyde, nine parts water) and preserving them in a barrel with alcohol 70–80%. About every month Cunha and Nascimento visited all localities and assembled the material that had been collected. In this way, specimens collected during daily activities (including preparing agricultural ground) could easily be collected and added to the collection, including species that were rare, or which, due to fossorial habits or because of being very cryptic, are difficult to obtain during normal herpetological fieldwork. The herpetological collection of MPEG thus increased rapidly in a short time. This system was especially effective for snakes, but also for amphisbaenians and caecilians. It also yielded a large series of the lizard *Stenocercus dumerilii* (Steindachner, 1867), which until then was known from only a few specimens. This series formed the basis for a publication in which the species was redescribed (under the name *Ophryoessoides tricristatus*) and notes on its ecology and distribution were provided (Cunha 1981).

The abundant material obtained during these collections formed the basis for the pioneering and seminal series "Ofidios da Amazônia" by Cunha and Nascimento and numbered I–XXII (number I was written by Cunha, number XII had A. R. Hoge as a co-author), which appeared between 1967 and 1991. Number X ("As cobras da região leste do Pará," Cunha and Nascimento 1978) is of special interest because it described the snake fauna of a large Amazonian area and became a classic for the study of Amazonian snakes. In 1993 a second book was published that was presented as a revised second edition of the 1978 version, but in reality it is a complement to the 1978 book. It contains additional data and different photos (black and white), and it dealt with 87 species, 12 more than in the 1978 paper. This was the last publication in herpetology by Cunha (and also of Nascimento). The impact of the series of papers on lizards (1958–1981) and snakes (1967–1991) outside of Brazil was not optimal, because of distribution problems of the MPEG journals in which most papers were published; issues sometimes took years before they reached foreign libraries. Another problem was that Cunha was not very well connected outside Brazil and had little correspondence with foreign colleagues (he wrote only in Portuguese). Possibly these papers on Amazonian lizards and snakes might have had a greater impact had they been written in English. However, within Brazil the importance of especially the series on snakes was well recognized and due to the large interest in it the 1978 book soon was unavailable. The recognition of the value of the work by Cunha and Nascimento on Amazonian snakes was well expressed by Martins and Oliveira (1998), who dedicated their paper to "O.R. Cunha and F.P. Nascimento ……for their unparalleled contributions to the knowledge of Brazilian Amazonian snakes, including natural history, and the immense collection of snakes at the MPEG, an invaluable source of natural history information for years to come." This statement is still very appropriate, as shown by the present use of the MPEG collection by many students and researchers for taxonomic, anatomical, and ecological studies.

At the time of Cunha's retirement, the herpetological collection contained 38,000 specimens, an increase of nearly 60 times compared with the number in 1965. It was the largest collection of Amazonian material and the third largest in Brazil. The herpetological collection continued growing after Cunha's retirement and at the moment contains approximately 86,000 specimens, now with amphibians forming the largest group, followed by lizards and snakes. It ranks among the three largest in Brazil and the largest concerning Amazonian herpetofauna.

When in 1985 the herpetological collection was transferred to a new building at the Research Campus of MPEG at the Avenida Perimetral, on the outskirts of Belém, Osvaldo Cunha preferred to stay in his room at the Parque Zoobotânico of MEG, in the central part of Belém, and thus became separated from the herpetological collection. This was an important decision, because after 1985 his herpetological work practically came to a standstill, and until 1993 only four herpetological papers were published, in two of which he was third author.

The publications on the herpetofauna of Amazonia by Cunha and Cunha & Nascimento constitute a good base for more elaborate studies on the reptiles of Amazonia, which are being developed by researchers of MPEG and more recently also of the Federal University of Pará, together with graduate and master's students and doctoral candidates in herpetology. At least in part, Osvaldo Cunha was responsible for the presence of these researchers in these two institutions in Pará. Without his pioneering work and the herpetological collection that he built, the MPEG certainly would not be as attractive for herpetologists from other parts of Brazil and abroad as it is now.

Osvaldo Cunha retired in 1990 at the age of 62 years, but continued working in another area that held his interest: the history of MPEG and of the scientists who worked there. One of the most interesting papers by Cunha prepared during that time (Cunha 1991) was about the naturalist Alexandre Rodrigues Ferreira, who traveled in Brazilian Amazonia between 1783 and 1792. In this paper Cunha not only writes about Rodrigues Ferreira, but includes information about other naturalists who traveled in Amazonia during the 19th century, and maps of the trajectories covered by them. This publication is a rich source of information about the work of the traveling naturalists who collected the first data about fauna and flora of Amazonia. Unfortunately, the loss of sight prevented him from completing several biographies and other manuscripts.

Between 1954 and 1988 Cunha published many texts in Belém newspapers, both about zoology and about the history of science, indicating his interest in providing knowledge to the general public.

At first meeting, Osvaldo Cunha appeared to be a closed and difficult person, but those who had the opportunity to have more contact with him came to know him as an attentive person with a phenomenal memory, who could talk for hours about many subjects, apart from herpetology. With the death of Osvaldo Cunha, the MPEG lost a great researcher and an interminable source of knowledge about the museum and its personnel.

This "In memoriam" was largely based on the biography of O. R. Cunha published in 1991 by Francisco Paiva do Nascimento in the Boletim do Museu Paraense Emilio Goeldi, Zoologia 7(1), a number dedicated to Cunha, as well as on our contacts and long conversations over the years. One of us (TCSAP) arrived in MPEG in 1983, with a Masters degree in Zoology, but without any experience with Amazonian herpetofauna. She worked with Cunha and Nascimento, a partnership that resulted in three joint publications, and, more than that in learning, friendship, and admiration. The senior author (MSH) had regular correspondence with Osvaldo Cunha about the herpetofauna of the Guianan region, and in 1976 had the opportunity to meet him personally during a one week visit to the MPEG collections. After that, when he did more fieldwork in Brazil and finally when he moved there, the contacts became closer.

In conclusion, we present a list of species described by O. R. Cunha, patronyms, honors he received, and a list of his most important herpetological publications. This list of publications was copied from Nascimento (1991 [see reference above]), with some alterations and additions, mainly of papers published after 1990. Apart from the papers listed, Cunha participated as a co-author in seven papers on chromosomes of Amazonian reptiles. A complete list of Cunha's papers can be found in Hoogmoed et al. (2011).

In Memoriam: Bern W. Tryon (1947–2011)

Bern W. Tryon, well known zoo herpetologist and Bog Turtle field researcher and biologist, died peacefully at home on 6 May 2011 after a long battle with cancer. He was 64. Bern was the Director of Animal Collections/Herpetology at the Knoxville Zoo and Director of the Tennessee Bog Turtle Project based in east Tennessee. He was preceded in death by his parents Willard William and Helene Kish Tryon. He is survived by his daughter Katherine Tryon and granddaughter, Sophia, of Richmond, Virginia.

Bern was born in Newburgh, New York, on 11 March 1947. The family moved to Terre Haute, Indiana, where Bern's childhood was happily spent collecting butterflies and searching for amphibians and reptiles, a hobby that became his life's work. One of his fondest memories occurred at the age of 10, when his family took him to Florida, and they visited Ross Allen's Reptile Institute in Silver Springs. He was thrilled to be able to talk to Ross Allen during the visit, and bought his first snake, an Eastern Indigo Snake, the first of many species he would care for over the next 54 years. Bern moved to Aiken, South Carolina, in 1969, and found work at the Savannah River Ecological Laboratory under the tutelage of Whit Gibbons and I. Lehr Brisbin. It was during this period that he honed his "search image" while collecting reptiles for the laboratory, and visited the famed "Okeetee" area in Jasper Co., South Carolina, for the first time.

FIG. 1. Bern Tryon tracking Bog Turtles in 2009 at the Ripshin Bog, a privately owned property in Tennessee. Over the past 20 years, 167 head-started Bog Turtles from the Knoxville Zoo program were released at this site.

In 1971, Bern received a BS in Biology from Gardner-Webb University in North Carolina. Upon graduating he began his illustrious zoo and herpetological career with the Atlanta Zoo (Zoo Atlanta), Atlanta, Georgia, as Reptile Keeper/Senior Reptile Keeper (1971–1974). His next zoo position was Assistant Supervisor/Supervisor of Reptiles at the Fort Worth Zoos (1974–1980), and then Supervisor of Herpetology at the Houston Zoo (1980–1984). Bern moved to the Knoxville Zoo in 1984, where he held the following positions: Curator of Herpetology (1984–2009), General Curator (1994–1997), and Director of Animal Collections/Herpetology (2000–present).

Bog Turtles (*Glyptemys muhlenbergii*) became one of Bern's major passions when he found his first in a Henderson Co., North Carolina, study site with long-time friend Dennis Herman in 1982. He continued to assist Herman in Bog Turtle field work after he moved to Knoxville in 1984. His decision to have the Knoxville Zoo become a leader in Bog Turtle captive propagation and conservation came to fruition when he converted an old outdoor alligator exhibit into a world class Appalachian Bog ecosystem replete with live bog plants and a core breeding group of Bog Turtles. The spring of 1986 became an important time in his quest to further the zoo's involvement in Bog Turtle conservation when the first Bog Turtle ever reported in Tennessee was found (Herman and Warner 1986). Bern found his first Tennessee Bog Turtle three days after the first had been discovered, and he laid the groundwork for what was to become the most complex and extensive Bog Turtle study ever attempted. An offshoot of his Tennessee capture-mark-recapture study also took root in 1986 when he decided to initiate a captive propagation, head-starting, and release project in a Carter Co., Tennessee mountain bog. This large bog site was determined to be devoid of Bog Turtles after nearly 50 hours of intensive search during 1986 and early 1987. There was initial skepticism and controversy from some quarters regarding the validity of such a project. Not to be deterred, and in single-minded fashion, Bern put together a coalition of partners to support such an endeavor, the likes of which had never been attempted for Bog Turtles. This partnership consisted of the Knoxville Zoological Gardens, American Association of Zoos and Aquariums (AZA), U.S. Fish & Wildlife Service, Tennessee Wildlife Resources Agency, and The Nature Conservancy. The first cohort of turtles was released in the site in 1991, with 167 released through 2011 (Fig. 1, 2). He began a radio tracking study and a trapping regime, with his project assistant Lynn Easton, to maximize recapture efforts of the released turtles. After years of collecting capture and movement data, and three years before he died, Bern experienced the thrill of finding the first neonates and nests in this artificially established population. He now had the evidence needed to validate this as a viable option for Bog Turtle conservation. The lesson he would try to pass along to skeptics and supporters alike, was that these types of studies are long-term—or life long, as he would say—and one should not expect instant results.

Bern's zoo career spanned 40 years, during which time he wrote over 30 papers and articles relating to herpetological techniques, reproductive biology, and conservation. Many of the species that were of special interest to Bern, as well as the places he frequented for field work, were heavily influenced by the writings of Carl Kauffeld, former reptile curator of the Staten Island Zoo. Two of Carl's books—*The Keeper and the Kept* and *Snakes and Snake Hunting*—were treasured by Bern and most of his contemporaries, and had significant impact on his herpetological pursuits. These books led him on many trips to the Trans-Pecos region of west Texas, the mountains of southeastern Arizona, and of course Okeetee, South Carolina. His most prolific publishing years were during his tenure at the Fort Worth Zoo (1974–1980) and reflected some of the Kauffeld influence. And though Bern was generally considered a turtle man, he was also a snake man

par excellence with exceptional husbandry skills. He had a touch with snakes that was intuitive, almost instinctive, and was adept at enticing recalcitrant feeders. Many of his charges attained longevities unheard of at the time in captivity. He conducted some of the pioneering research on the reproductive biology of the Gray-banded Kingsnake (*Lampropeltis alterna*) and Ridgenose Rattlesnake (*Crotalus willardi*), both of which resulted in notable publications. Both species would become enduring passions of Bern's, in fact he was so taken with *C. willardi* madness that he once attended a Halloween party with his face painted with the characteristic *willardi* flash markings. His fascination with *L. alterna* would also become an obsession, taking him on numerous trips to west Texas to search for the elusive quarry. It took nine trips before he bagged his first one, ironically by field collecting and not road riding as was the tried and true method. His papers on aquatic turtle husbandry and incubation of reptile eggs—based on work at the Fort Worth Zoo—are considered classics, still referenced today, some 35 years after publication. His magnum opus was the 1980 publication on the reproductive biology of the West African Dwarf Crocodile (*Osteolaemus tetraspis*), which still stands as one of the seminal papers on crocodilian parental behavior, and is widely regarded as one of the definitive works on that species. Evidence that the seeds were sown early for what was to later become his life's work came in 1976 when he published a paper on breeding and rearing the Bog Turtle in captivity. During his tenure at Fort Worth, the zoo developed a reputation for designing some highly naturalistic herp exhibits. Bern had a keen eye for exhibit work, and several of his montane rattlesnake exhibits done in the late 1970s were still in use into the 1990s. Under Bern's leadership, the Herpetology Department at the Fort Worth Zoo received two AZA Significant Achievement Awards for breeding West African Dwarf Crocodiles and Angel Island Chuckwallas (*Sauromalus hispidus*). In 1985, during Bern's tenure at the Knoxville Zoo, his department was honored with the prestigious AZA Bean Award for breeding the Papuan Python (*Apodora papuana*).

Bern did not venture too far outside the U.S., but in 1984 accompanied Jonathan Campbell and Rick Hudson to Costa Rica, uniting three successive generations of Fort Worth Zoo Assistant Herp Curators on one expedition. A herpetological catastrophe was narrowly averted as the three were riding on the tailgate of a pickup when a driver nearly rear-ended their vehicle at high speed, swerving at the last second to miss them.

He was affiliated with various professional organizations such as the AZA, Turtle Survival Alliance (TSA), IUCN Tortoise and Freshwater Turtle Specialist Group (TFTSG), and AZA Chelonian, Crocodilian, and Snake Taxon Advisory Groups. He served as the Section Editor (Herpetological Husbandry) for *Herpetological Review* from 1979 to 1992. He was also on the Editorial Review Board for *Chelonian Conservation and Biology* (1993–2005), and was elected to the SSAR Board of Directors for1992–1994). He was the Tennessee Director for Project Bog Turtle since 2003.

Bern's hard work and perseverance paid off as he received numerous prestigious awards for his outstanding contributions to conservation and research for the bog turtle in the Southeast from the U.S. Fish and Wildlife Service, Project Bog Turtle, and the AZA. Then in 2010 he received one of the first Lifetime Achievement Awards for Turtle Conservation from the TSA and the TFTSG, in recognition of his long-standing commitment to the southern Bog Turtle. Bern believed that southern Bog Turtle work was under-funded compared to the northern form, and to help remediate this situation he bequeathed his substantial herpetological library to the TSA to establish an endowment specifically for Bog Turtle work in southern states.

Although only a handful of people had the opportunity to see the real Bern Tryon outside of his professional realm, the personal relationships that he cultivated from entry level keepers to executive directors were unmatched. Tradition dictates that keepers usually avoid their curators, or if the encounter looks imminent…look busy. Bern was quite the opposite. If there was a waft of blue pipe smoke in the air, then that was the queue to follow the smell to Bern, where the reward would be casual conversation ranging from rich herpetological history to cutting edge husbandry techniques. Bern recognized the value in these interactions and went to great lengths to keep that as a necessary part of the daily routine.

Bern's commitment to herpetological conservation was uncompromising and with his passing the turtle community has

lost one of its staunchest allies. He will forever be remembered for his dedication and passion for herpetology, his laid-back, easy-going personality, his wonderful sense of humor, and being a good father and grandfather. He never lost that sense of enthusiasm in the field, and we can still see that twinkle in his eyes whenever he found a Bog Turtle or a big Eastern Diamondback. He was a great friend to his herpetology buddies who met each spring for over 40 years to search for reptiles in the Okeetee area of South Carolina. He will be greatly missed by all those who knew him.

The Herpetology Collection at the North Carolina State Museum of Natural Sciences

With at least 92 amphibian and 72 reptile species, North Carolina has long attracted the attention of herpetologists, including such pioneers in early North American herpetology as John Edwards Holbrook, Edward Drinker Cope, and Emmett Reid Dunn (Martof et al. 1980; Beane et al. 2010). The herpetological richness of the state is attributed to its great diversity in topography, climate, and vegetation (Martof et al. 1980; Beane et al. 2010), and the herpetofauna consists of an admixture of temperate northeastern U.S. and subtropical southeastern U.S. taxa. The significance of North Carolina's herpetofauna is reflected in the amphibian and reptile collection at the North Carolina State Museum of Natural Sciences (NCSM), one of the largest and most complete regional collections in the United States.

The collection was started in the late 1800s by North Carolina naturalists and brothers Clement Samuel (C. S.) Brimley and Herbert Hutchinson (H. H.) Brimley. H. H. became the museum's first full-time curator in 1895 and its first official director in 1928 (Cooper 1979; Martin 2001). While C. S. was never officially employed by the museum, he collected or otherwise acquired many of the specimens that would later form the beginning of its amphibian and reptile collection. The oldest specimen known to be in the holdings, NCSM 431, is not a North Carolina specimen, but rather a Gulf Coast Toad (*Bufo valliceps*) collected in Waco, McLennan County, Texas, on 30 March 1895 and received by C. S. from an unstated collector (probably John K. Strecker, Jr., from whom he acquired several other specimens from that locality).

Most of the specimens have been accumulated since the 1960s, when William M. Palmer (Fig. 1) began caring for the fish, amphibian, and reptile collections. Palmer began working part-time for the museum in 1951, and was hired full-time as Curator of Zoology in 1963. Prior to then, the amphibian and reptile collection consisted of an assortment of uncatalogued specimens identified by museum accession numbers or associated data labels. In 1962, Palmer acquired archival catalog ledgers, fluid-resistant specimen tags, and adequate storage containers, and on 15 December 1962 he designated NCSM 1 to a *Necturus lewisi* (the first 20 specimens catalogued were of this species, a North Carolina endemic described by C. S.), thus initiating the cataloguing system still used today.

Alvin L. Braswell (Fig. 1) joined the staff in 1968, first as an intern, then as a part-time assistant. He became permanent staff in 1974 as Collection Manager of Lower Vertebrates, and then as Curator of Lower Vertebrates. Palmer and Braswell held joint positions as curators until Palmer retired in 1995. Palmer continues to work in the collection today in the supporting role of Emeritus Curator of Herpetology. Jeffrey C. Beane (Fig. 2) was hired in 1985 as a Research Technician and has held the position of Collection Manager of Herpetology since 1995. Most recently, Bryan L. Stuart joined the museum in September 2008 as Curator of Herpetology when Braswell moved into an administrative position as the museum's Deputy Director. At the time of writing,

all four generations of herpetologists, representing at least 114 person-years at the museum, are actively serving the institution (Fig. 3). Palmer, Braswell, and Beane have dedicated their careers to documenting the natural history, distribution, and conservation status of the amphibians and reptiles of North Carolina and adjacent states, and these three individuals have together built most of the collection. Stuart has added an interest in molecular systematics and species delimitation, as well as an international perspective (Southeast Asia and Central Africa), to herpetological research at the museum.

Despite the name similarity, the museum is not officially part of North Carolina State University, although the museum and university maintain a close association and many of the museum's curators have adjunct faculty appointments at the university. The institutional acronym of NCSM, used in cataloging specimens, is based on the earlier name of "North Carolina State Museum" (Leviton et al. 1985). The official name of the institution is now North Carolina State Museum of Natural Sciences, although the word "State" is often omitted from the institutional title for marketing purposes, such as on the museum's website.

As of June 2011, NCSM's amphibian and reptile collection contains over 78,300 cataloged records consisting of approximately 200,000 specimens. Approximately 80% of the collection consists of North Carolina material, although at least 45 states, 24 countries and 650 species are represented. Other states with substantial representation include California, Delaware, Georgia, Florida, Louisiana, New Jersey, New York, South Carolina, Tennessee, and Virginia. Other countries with substantial representation include Gabon, Laos, and Vietnam. The collection contains paratypes of seven amphibian taxa (*Eurycea chamberlaini, E. junaluska, Leptolalax aereus, L. bidoupensis, Leptobrachium leucops, Rana palustris mansuetii,* and *Rhacophorus vampyrus*) and two reptile taxa (*Ophisaurus mimicus* and *Nerodia sipedon williamengelsi*), and the holotype of one amphibian (*Leptobr. leucops*). From the 1960s to the late 1980s, then-curator Palmer transferred additional types (including holotypes) to the Smithsonian Institution National Museum of Natural History and the American Museum of Natural History when the long-term persistence of the collection appeared uncertain.

PHOTO BY DANIEL J. LYONS

FIG. 2. Jeffrey C. Beane in 1987 with preserved Pine Snakes (*Pituophis melanoleucus*) in the amphibian and reptile collection at the North Carolina State Museum.

Major acquisitions into NCSM's amphibian and reptile collection include the collections of Duke University (the late Joseph R. Bailey et al.), Virginia Commonwealth University (Charles R. Blem et al.), State University of New York at Binghamton (Ted D. Murphy et al.), the University of North Carolina's Institute of Marine Sciences (Frank J. Schwartz et al.), and the personal collections of the late Elmer E. Brown, Richard C. Bruce, Rufus W. Gaul, Jr., the late Julian R. Harrison III, and David L. Stephan. Numerous other individuals have made substantial contributions to the collection, often over many years; these include Stanley L. Alford, Rudolf G. Arndt, Michael E. Dorcas and students (Davidson College), Richard R. Montanucci, L. Todd Pusser, Thomas J. Thorp, the late George Tregembo and family, and numerous members of the North Carolina Herpetological Society, an NCSM affiliate group.

NCSM's amphibian and reptile collection formed the basis for three significant books on the state's herpetofauna. *Amphibians and Reptiles of the Carolinas and Virginia,* first published by Martof et al. (1980) and recently revised by Beane et al. (2010), is a guide to all the amphibian and reptile species of the state (and South Carolina and Virginia), including color images and maps of species. *Reptiles of North Carolina,* published by Palmer and Braswell (1995), is a comprehensive volume on all aspects of the biology of the state's reptiles. Other popular publications based heavily on the collection include a booklet on North Carolina's venomous snakes (Palmer 1974; revised by Braswell et al. 2003), a book highlighting NCSM and its collections (Martin 2001), and a book and CD guide to North Carolina anurans and their calls (Dorcas et al. 2007). Innumerable scientific publications have extensively utilized the NCSM amphibian and reptile collection, among them many student theses, such as those by Davis (1968), Fedak (1971), Braswell (1977), Reynolds (1980), Williams (1983), Gaul (1996), and Mebert (2003).

Since 1998, the amphibian and reptile collection has been housed at the museum's Research Laboratory (Fig. 4), a 20,296 square foot facility that was specifically designed for housing the museum's "wet" collections (invertebrates, fishes, amphibians and reptiles, and some fluid-preserved birds and mammals). The "dry" collections (most birds and mammals, paleontology, and geology) are housed approximately six miles away, in the main museum building in downtown Raleigh, where exhibits and events open to the public are also located. The amphibian and reptile specimen range is a 4,709 square foot room maintained at a constant 20ºC (68ºF) and 45 ± 2% relative humidity, without windows and with ultraviolet light filters on overhead fixtures. A Honeywell MDA Scientific Midas alcohol gas sensor system in the range trips an alarm if alcohol is detected from a spill. The collection maintains fluid-preserved specimens, skeletons, skins, dry taxidermy mounts, stomach contents, photographic vouchers, and other materials, as well as supporting documentation such as field notes, data sheets, and correspondences. Most amphibian eggs, amphibian larvae, and reptile hemipenes are stored in buffered 8-10% formalin; most other wet specimens are originally fixed in formalin and subsequently switched to 70% ethanol for permanent storage. Most wet specimens are stored on open metal shelves in glass jars, vials, or crocks; some larger specimens (such as crocodilians, turtles, and snakes) are in stainless steel tanks on wheels or in plastic buckets or barrels. Dry materials, such as skeletons, skins, and taxidermy mounts, are housed in glass containers or archival-quality storage boxes with lids. Taxa are arranged phylogenetically by order and family, and then alphabetically within family by genus, species, subspecies, and county. Type specimens, catalog ledgers, and some original field notes and other records are stored in fireproof cabinets. Adjacent to the range is a herpetology "wet lab" with a fume hood, microscopes, computers, and other equipment and supplies needed for processing, curating, examining, and loaning specimens. Offices for herpetology personnel are in close proximity to the wet lab and collection range. Tours of the facility are frequently conducted for interested individuals and groups such as university classes.

FIG. 4. A view down the central aisle of the amphibian and reptile collection at the Research Laboratory, North Carolina State Museum of Natural Sciences, 22 June 2011.

Two major initiatives are underway in the collection. The first is to develop genetic resources in the amphibian and reptile collection to make tissues and DNA extractions available to users for molecular genetic analyses. The vouchered tissue collection has rapidly grown from a handful of tissues in 2008 to over 1,300 tissues in June 2011, and tissues now account for a large percentage of loan requests from the scientific community. A National Science Foundation-funded project, incepted in April 2011, provides for storing these tissues in labeled and barcoded cryogenic vials in an ultra-cold (-80ºC) freezer to minimize thermal degradation.

The second major initiative is to database and georeference the catalog ledgers to allow rapid and remote access of the collection's holdings by researchers, resource managers, the public, and other user groups. The development and success of the museum's database structure was extensively treated by Hogue and Raine (2006). At the time of writing, the amphibian and reptile collection database is online (http://collections.naturalsciences.org), but only a portion of the collection is in the database. Users should be aware that this digitization effort is a work-in-progress, and curatorial staff should be contacted for a complete list of holdings. The museum is a participant in HerpNET (http://herpnet.org), and plans are to have the digitized portion of the collection on the HerpNET portal by 2012. Readers are encouraged to consider utilizing the NCSM herpetological collection for their future research needs.

Plural versus Singular Common Names for Amphibian and Reptile Species

Although scientific names are the accepted means of referring to species in the scientific literature, common names continue to serve important functions in both scientific and popular communication. That fact is evident from the inclusion of both scientific and common names in checklists published by various taxonomically specialized scientific societies (e.g., American Ornithologists' Union 1998 [birds]; Baker et al. 2003 [mammals]; Crother et al. 2008 [amphibians and "reptiles"]; Nelson et al. 2004 ["fishes"]). In this context, a relatively minor yet somewhat radical change concerning the use and formation of common names in a recent checklist of iguana species (Iguana Taxonomy Working Group 2011) deserves explanation. The change is minor in that it involves only a single letter, "s," reflecting the plural instead of singular nature of each name, but it is radical in that it affects the names of all species in the checklist and breaks a long-standing tradition. A description of the rationale for this change was outside of the scope of the checklist, and therefore I, as the instigator, am presenting the rationale here. I hope to convince herpetologists (and biologists in general) that the traditional use of singular common names as the equivalents of the scientific names of species is inconsistent with modern species concepts and the meanings of the words from which the names are formed, and therefore, that plural common names should be used instead. Although some may consider the inconsistency to be insignificant (and thus the proposed solution to be one to a "non-problem"), it reflects a fundamental and inappropriate assumption about the basic nature of taxa.

The term "common" (in "common name") is used here to mean "ordinary" or "familiar" (as opposed to "widespread" or "general") in the sense of being composed of ordinary or familiar words; it is therefore roughly synonymous with "vernacular," meaning "of the everyday language or dialect of a group of people." The common names used by different groups of people can be distinguished by specifying a region, country, or language (e.g., "English common names"). Other properties of common names can also be conveyed by using appropriate adjectives (e.g., "standard English names" for English common names proposed in an attempt to standardize usage). I will restrict considerations in this commentary to English common names, though they likely apply to those of other languages. With one exception, I will also restrict my comments and examples to names of amphibian and reptile species, though they obviously apply to those of other taxa as well.

MODERN SPECIES CONCEPTS AND THEIR IMPLICATIONS FOR COMMON NAMES

Although debate continues concerning the precise definition of the species category (reviewed by de Queiroz 1998; Mayden 1997; Wilkins 2006), all modern species concepts equate species more generally with population level lineages—that is, with populations or metapopulations (groups of connected populations) that extend through time as the result of ancestry and descent among their component organisms (de Queiroz 1998, 1999, 2007). Implicit in this general concept of species is the view that the species category is a level in the hierarchy of biological organization (Brown 1995; de Queiroz 2011; Mayr 1982), which includes at least cells, organisms, colonies, and populations/species, and perhaps entities at lower levels (e.g., genes) and higher levels (e.g., communities) as well. In this hierarchy of biological organization, entities at higher levels (e.g., species) are made up of those at lower levels (e.g., organisms).

In agreement with the recognition of a hierarchy of biological organization, different names are usually used for entities that occupy different hierarchical levels. For example, "Lonesome George" is the name of an organism that is part of the species named "*Chelonoidis* (formerly *Geochelone*) *abingdonii*." The common names of species, however, are often used in a way that is inconsistent with such distinctions; that is, the same common names are often used to refer both to individual organisms and to the species of which they are parts. For example, it would not be unusual for someone to say, "I saw a zebra-tailed lizard near Pisgah Crater in the Mojave Desert," using the name "zebra-tailed lizard" to refer to an individual organism. It would also not be unusual for someone to say, "The zebra-tailed lizard occurs in the Mojave Desert," using the same name, including the singular number, to refer to an entire species. This second use, however, is inconsistent with modern species concepts and the meanings of the words from which the common name is formed.

The common names of amphibian and reptile species are often formed by adding adjectives (e.g., "red-cheeked," "Sonoran"), including participles (e.g., "barking") and attributive nouns (e.g., "canyon," "rat"), or possessive nouns (e.g., "Baird's") to base names. Those base names—words such as "frog," "salamander," "turtle," "lizard," "snake," and "alligator"—are common nouns in that they refer to the members of groups of organisms. Those groups are now commonly conceptualized as the classes or sets of organisms that make up particular clades, or sometimes paraphyletic groups (e.g., "lizards"). A snake, for example, is an individual organism; it is an individual member of the set of organisms making up the clade Serpentes or Ophidia. Therefore, when we refer to a single organism in this set, we use the singular noun "snake" (e.g., "Amy anaesthetized a snake before performing surgery on it"), and when we refer to several such organisms, we use the plural noun "snakes" (e.g., "Steve has been radio-tracking 10 snakes at the same time").

When common names are formed using common nouns of the kind just described, it is inconsistent to use the singular form of those names as equivalents of the scientific names of species. The reason that this use is inconsistent is that singular common names properly refer to individual organisms, not to entire species, whereas scientific names of species properly refer to entire species, not to individual organisms. A zebra-tailed lizard, for example, is not a species; it is an organism that is a member

KEVIN DE QUEIROZ
Division of Amphibians and Reptiles, National Museum of Natural History, Smithsonian Institution, Washington, DC 20560-0162, USA
e-mail: dequeirozk@si.edu

or part of a species (*Callisaurus draconoides*). Conversely, *Callisaurus draconoides* is not a lizard, zebra-tailed or otherwise; it is a species the organismal parts of which are (zebra-tailed) lizards. Therefore, because species are almost always composed of more than one organism, the name "*Callisaurus draconoides*" is not equivalent to "[the] zebra-tailed lizard" but to "zebra-tailed lizards." And thus, the incorrectly stated sentence "The zebra-tailed lizard occurs in the Mojave Desert," is correctly stated using either a singular species name: "*Callisaurus draconoides* occurs in the Mojave Desert," or a plural common name: "Zebra-tailed lizards occur in the Mojave Desert."

Interestingly, the problem I am discussing is largely restricted to the common names of species. Analogous inconsistencies involving the common names of higher taxa (clades) are rare to non-existent. For example, it is not customary to equate the name "Squamata" with "[the] lizard" but with "lizards." Nor is it customary to equate "*Phrynosoma*" with "[the] horned lizard" but with "horned lizards." Nevertheless, it is customary to equate "*Phrynosoma solare*" with "[the] regal horned lizard," though consistency dictates that we ought to equate it with "regal horned lizards." All of the taxa just mentioned, whether clades or species, are composed of more than one organism.

SCIENTIFIC NAMES AND COMMON NAMES OF SPECIES

In contrast to English common names, the scientific names of amphibian and reptile species (as well as those of species in other clades) are commonly formed from Latin or Latinized words. Those words are often common nouns in their original language (e.g., "*rana*" is Latin for "frog"), but as scientific names, they are treated differently. In both popular and scientific discourse, the scientific names of species are commonly used in the singular, implying that they refer to species as wholes rather than to the organismal parts of species. In agreement with the treatment of scientific species names as singulars, several authors have argued that the scientific names of species are proper nouns (e.g., Ghiselin 1974; Hull 1976). Proper nouns, by definition, refer to individual entities (in this case, particular species) and thus are necessarily singular. Given that scientific names are singular, it is correct to say "*Plethodon petraeus* has a restricted distribution" but incorrect to say "*Plethodon petraeus* have a restricted distribution."

The use of scientific names as proper nouns is perhaps most natural in languages that are relatively distantly related to Latin (e.g., English and German more so than Spanish and Italian). Because the Latin or Latinized words from which scientific names are formed are more likely to be unfamiliar to speakers of such languages, it is natural to treat them as proper nouns, that is, as words (names) that simply refer to individual things, rather than common nouns, which refer to sets or classes of individual things and therefore often describe properties possessed by the members of those sets or classes. Just as the name "Doris Cochran" simply refers to a particular person, the name "*Apalone mutica*" simply refers to a particular species. That the name "Doris Cochran" means "of the sea" and "red" or "crimson" and the name "*Apalone mutica*" means "soft" and "unarmed" is irrelevant to their functions of referring to an individual person or species. That is to say, scientific names can be (and perhaps often are) used to refer to particular species regardless of whether the users of those names know or care about the meanings of the Latin or Latinized words from which the names are formed. Consequently, scientific names need not be descriptively accurate. For example, just as the name "George" works perfectly well for referring to a person who is not a farmer, the name "*Coluber constrictor*" works perfectly well for referring to a species whose members do not commonly constrict their prey.

Like the scientific names of species, the common names of species are sometimes interpreted as proper nouns (e.g., Parkes 1978; Potter 1984). That interpretation, however, is inconsistent with certain practices involving common names. Rather than simply referring to species, common names often describe one or more properties of species or their component organisms. This situation is reflected in changes in common names to improve their descriptive accuracy, a practice that is expressly forbidden with scientific names. For example, the common name "poison arrow frog" was changed to "poison dart frog" (and "dart-poison frog"), and the names "Mexican hook-nosed snakes" and "plateau hooked-nosed snakes" were changed to "eastern hook-nosed snakes" and "western hook-nosed snakes" (Crother et al. 2008), in all cases to improve descriptive accuracy. In contrast, the name "*Coluber constrictor*" cannot be changed for the sake of improving descriptive accuracy. Although that rule is imposed by a formal system of zoological nomenclature, which does not apply to common names, the way that the system operates reflects the fact that the primary function of scientific names is simply for referring to taxa and not for describing the properties of their included organisms.

The interpretation of common names as proper nouns is also inconsistent with the meanings of the words from which they are formed. Because the base words from which common names are formed are common nouns (e.g., "gecko"), modifying them with descriptive adjectives (e.g., "banded") and/or possessive nouns (e.g., "Switak's") creates names that are also common nouns. Declaring them to be proper nouns or capitalizing them does not change that fact. Using them in the singular goes further toward making them function as proper nouns in that the species to which they refer are individual population level lineages; however, many uses of common names in the singular are inconsistent with their interpretation as proper names of species. For example, the statement "The Eastern Red-backed Salamander is a small species" is either incorrect or incorrectly stated. If the name "Eastern Red-backed Salamander" is the name of a species, that species (*Plethodon cinereus*) is not small: It has an extensive geographic distribution (Highton and Webster 1976), and its component organisms are extremely abundant, resulting in a high species biomass (Burton and Likens 1975). Alternatively, if the statement is about the average body size of the salamanders that make up the species and not about the species as a whole, then the proper name of the species should not be used. That is, it would be more appropriate to say "Eastern red-backed salamanders are small animals." Again, this confusion results from using a word that refers to a kind of organism as the name of a species.

USE OF SINGULAR COMMON NAMES AS A HOLDOVER

The likely explanation for the inconsistent but traditional use of singular common names for species is that it is a holdover from an earlier age. This practice originated in the pre-evolutionary era (see Daudin 1802–03 and Shaw 1802 for French and English examples), when species were conceptualized at least partly as essences or types (e.g., Hull 1965; Mayr 1976, 1982). Species were also conceptualized as self-perpetuating groups of organisms (de Queiroz 2011); however, without the principle of

evolution, the similarity and reproductive compatibility among their members was explained by their being of the same essence or type in the mind of their creator (Darwin 1859). Under essentialism, the name of a species is the name of an essence, an eternal, abstract Idea or Form of which living organisms are its concrete manifestations (Hull 1965). Under typology, a species is a type, a class or category of entities (i.e., a group defined by a set of shared characteristics) of which organisms are its instances or examples. In either case, the essence or type of a species consists of those properties that are necessary and sufficient for species membership, and traditionally, those properties took the form of organismal traits (de Queiroz 1992, 1995; Sober 1980). Thus, species were conceptualized either as eternal, ideal organisms (essentialism) or as categories of organisms (typology). Also associated with these views is the idea that any traits that vary among the members of a species are incidental or accidental, since they are not important to the essence or type of the species.

The perspective just described contrasts with modern species concepts, according to which species are viewed not as essences or types but as population level lineages. That is to say, species are viewed as entities at a level of biological organization above the level of organisms, rather than as kinds or categories of organisms (and nothing more). Thus, under modern species concepts, organisms are parts or components of species rather than examples, instances, or manifestations of them. In addition, the organisms of a species are not required to share any particular set of traits (though they often do), and traits that vary among them are not viewed as intrinsically any less important than those that happen to be fixed. Moreover, as entities at a higher level of biological organization, species possess properties unique to the population level (e.g., population structure) in addition to the properties of their component organisms (e.g., body size). These and related views have been termed "population thinking" and are in contrast with those of essentialism and typology (e.g., Mayr 1959, 1976; O'Hara 1997; Sober 1980).

The use of singular common names in situations that, under modern species concepts, call for the use of plurals can be understood as a vestige of essentialist or typological species concepts. According to those doctrines, particularly when organismal traits are treated as the essential or defining characters, the name of a species (whether scientific or common) refers to a single organism: the single eternal, ideal organism of which tangible organisms are concrete manifestations, or the single concept of an organism possessing the properties that define the class of which actual organisms are examples or instances. To the extent that the essence or type of a species is conceptualized as an organism, it is appropriate to use singular common names, such as "the wood turtle," to refer to essentialist or typological species. Thus, the inappropriate use of singular common names based on terms that refer to organisms (e.g., "frog," "turtle," etc.) can be explained as a holdover from an era in which species were conceptualized as essences or types.

THE COMMON NAMES OF *HOMO SAPIENS*

Interestingly, people are less prone to using singular common names inappropriately when referring to our own species. Thus, we rarely, equate the scientific name "*Homo sapiens*" with the singular common names "[the] human" or "[the] human being;" instead, we use the plural common names "humans" and "human beings." For example, it would be normal to say, "Humans (*Homo sapiens*) are bipedal primates," but it would sound archaic to say, "The human (*Homo sapiens*) is a bipedal primate." Sometimes the singular common name "man" is used, though this practice is decreasing, presumably because it has inappropriate connotations with regard not only to number (singular versus plural) but also to gender. The singular common names "mankind" and "humankind" are also used. Those names, however, refer to the human species as a whole or the totality of human beings. Unlike the common names of amphibians and reptiles, they are never used to refer to individual people. For example, although one might say, "Henry is a tuatara who became a father at the age of 111," one would not say, "Leonard Stejneger was a mankind who published a monograph on the herpetology of Japan." Because we have different common names for referring to our own species as a whole and the organisms of which it is composed, inappropriate use of the singular "human" to refer to the human species as a whole is rare. In contrast, because humans have not developed separate common names for distinguishing between other species and their component organisms, inappropriate use of singular common names is not only common, it is the norm.

These patterns of use suggest that humans are less typological when referring to our own species than when referring to other species. Perhaps the reason is that we grant more importance to, or are more aware of, differences among individual humans than differences among the individual organisms of other single species. But regardless of the reason for this difference, the common names of other species, including those of amphibians and reptiles, ought to conform to the same standards that we adopt for the names of our own species. One way to achieve this would be to develop common names that clearly refer to other species as wholes rather than to their component organisms. For example, we could use names such as "the marine iguana species" or "marineiguanakind" for *Amblyrhynchus cristatus*. Up to the present time, however, such names have not been widely used for species other than *Homo sapiens*. As long as we continue to use common names that refer to kinds of organisms (i.e., names formed from base words such as "toad," "newt," "tortoise," "iguana," "boa," and "crocodile" without "species" or "-kind") as equivalents of the scientific names of species, those names should be used in the plural.

CAPITALIZATION

The considerations about common names described above also bear on the issue of capitalization. Under the interpretation of the common names of species as proper names (e.g., Parkes 1978; Potter 1984), those names are commonly capitalized. However, because common names are more appropriately interpreted not as the names of species as wholes but as names of the sets of organisms of which species (as population lineages) are composed (de Queiroz 1995), common names are not, strictly speaking, the names of individual species. Therefore, they are not proper nouns and need not be capitalized (compare Atkins 1983). This conclusion is consistent with the use of common names for the organisms comprising our own and other species ("humans," "dogs," "cats," etc.), which generally are not capitalized. I am not arguing however, that common names should not be capitalized. There may be other reasons for capitalizing common names, such as distinguishing the common names of species from general descriptions of organisms (e.g., "Green Frogs" versus "green frogs") and ease of recognition while reading (Nelson et al. 2002; Parkes 1978). However, the act of capitalizing a

common name does not thereby by make it a proper noun any more than does capitalizing a word in a section heading or at the beginning of a sentence.

CONCLUSION

In summary, plural rather than singular common names should be treated as equivalent to the scientific names of species. This practice is more consistent with modern species concepts and the meanings of the words from which common names are formed; it more clearly distinguishes between different hierarchical levels of biological organization; and it eliminates a vestige of typological or essentialist thinking. Moreover, although using plural common names for species may at first seem strange because it departs from a long-standing tradition, the change is relatively minor, it now has precedents in a checklist (Iguana Taxonomy Working Group 2011) and a taxonomic revision (Torres-Carvajal et al. 2011), and it should not be particularly difficult to become accustomed to.

Acknowledgments.—I thank B. Crother, H. Greene, B. Hedges, R. McDiarmid, and members of the Iguana Taxonomy Working Group (ITWG) for discussions related to this essay. Brian Crother also provided comments on the manuscript. Although the ITWG adopted use of plural common names in its checklist of iguana species, not all members (or the other people acknowledged) necessarily favored that convention, and even those who did may not agree with all aspects of the arguments that I have presented here.

Skilled Forelimb Movements and Extractive Foraging in the Arboreal Monitor Lizard *Varanus beccarii* (Doria, 1874)

Scientists and enthusiasts who have studied, kept, or observed monitor lizards (Varanidae: *Varanus*) for extended periods of time usually recognize that monitors possess considerable intelligence when compared to other reptile groups. Scientific testaments to their "higher intelligence" date back more than a century, with both Ditmars (1902) and Werner (1904) recognizing monitors as the pinnacle of lizard intelligence. Since then, many herpetologists have followed suit in this claim (e.g., Burghardt et al. 2002; Mertens 1942; Phillips 1994; Pianka and King 2004; Sweet and Pianka 2003), supported by research and behavioral observations of their own as well as a growing number of published accounts describing unusual and insightful behaviors in the group (see reviews by Horn 1999 and Krebs 2007). Formal research on the memory and learning capacities of monitors has also contributed to the general understanding of their intelligence (Loop 1976; Manrod et al. 2008).

Despite numerous published accounts on monitor behavior, the insight and behavioral complexity of some species are better understood than others. It is not surprising, given their size and conspicuousness when compared to smaller tree-dwelling taxa, that large terrestrial species (> 1.5 m in total length [TL]) account for most behavioral observations which have led to the idea of intelligence in monitors (Horn 1999; Krebs 2007). Even captivity-based studies on learning and behavioral complexity have focused primarily on large terrestrial species (e.g., Burghardt et al. 2002; Firth et al. 2003; Loop 1976; Manrod et al. 2008). Thus, little is known about the problem-solving abilities and behavioral specializations of the more diminutive monitors, particularly arboreal taxa belonging to the subgenera *Odatria* and *Euprepiosaurus*.

Within *Euprepiosaurus*, the *Varanus prasinus* complex is currently comprised of nine highly arboreal species (to ca. 100 cm TL) endemic to tropical lowland environments of northeastern Australia, New Guinea, and adjacent islands (Ziegler et al. 2007). Behavioral observations on these species in the wild (e.g., Clarke 2004; Irwin 1994, 1996; Pattiselanno et al. 2007; Whittier and Moeller 1993) and in captivity (e.g., Eidenmüller and Wicker 1992; Garrett and Peterson 1991; Hartdegen et al. 1999, 2000; Irwin 1996; Kiehlmann 1999) are rather limited, but specific references to insightful behaviors are scant (Holmstrom 1993). Krebs (1991) doubted the insight of *V. prasinus*, grouping it together with "less-specialized" monitor species on account of a presumed "lower specialized learning ability." This was before several published reports describing diverse prey-handling tactics used by the *V. prasinus* complex (Hartdegen et al. 1999, 2000; Kiehlmann 1999), which Greene (2004) later recognized as highly specialized behaviors. Here, we call special attention to the insight and behavioral complexity of the *V. prasinus* complex by describing a remarkable prey extraction behavior used by the Black Tree Monitor, *V. beccarii* (Doria, 1874), which demonstrates complex problem solving abilities, fine motor coordination, and skilled forelimb movements.

METHODS

History and husbandry of specimens.—An adult male (242 mm in snout to vent length [SVL]) and female (270 mm SVL) *Varanus beccarii* of unknown ages and of wild-caught origin have been maintained for several years in the private collection of RWM. Both specimens are housed in separate terraria each measuring 90 x 60 x 180 cm (l x w x h). A 6 mm thick sheet of acrylic doubles as a viewing window and access door for each terrarium. Each terrarium is furnished with large tree limbs and the walls are covered with cork sheeting and virgin cork slabs. Live *Pothos* plants provide additional cover. A basking spot of ca. 49°C is provided in each terrarium by outdoor Sylvania®100 watt halogen flood lamps, which also provide ambient lighting. Daytime ambient temperatures range in a vertical gradient from 23.8°C at the floor to 40.6°C at the ceiling. Nighttime ambient temperatures drop to 30°C. A small access door connecting the terraria is periodically opened to allow the monitors access to one another for breeding.

Since their acquisition, both specimens have been fed a rotating daily diet of *Zophobas morio* larvae, domestic crickets (*Acheta domesticus*), wood cockroaches (*Nauphoeta cinerea*), wax moth larvae (*Achroia grisella*), and frozen-thawed neonatal mice. Typical of many male monitor lizards in captivity, the male *Varanus beccarii* quickly developed a strong feeding response, and feeds aggressively from forceps. The female has remained timid with a weaker feeding response, and only occasionally accepts prey from forceps. Each specimen is fed at alternating locations throughout its terrarium to prevent habitual feeding locations and associated feeding aggression.

Beginning around April 2009, the male was infrequently offered neonatal mice and *Zophobas morio* larvae through a permanent 15 mm gap which had formed in the upper left corner of its terrarium between the acrylic door and the door frame. The gap, created by the warping of the acrylic door over time, was large enough to pass prey items through using forceps, but not large enough for the monitor to fit its head through.

OBSERVATIONS AND RESULTS

Initial behavioral observations.—On 25 January 2010, the male *Varanus beccarii* was fed a neonatal mouse through the gap in the terrarium door. Following its consumption, the monitor showed continued interest in the gap, now scented with mouse odor, by repeatedly tongue-flicking the area. After ca. 15 seconds of tongue-flicking, the lizard extended its right forearm through

the opening, and began reaching around the outside frame of the terrarium with its forehand. The lizard retracted its arm back into the terrarium, then after another series of tongue flicks, it extended its left forearm through the opening, performing the same reaching arm movements as before, but reaching a farther extension than with the right arm. This sequence of behaviors was repeated several more times over the next minute until the monitor apparently lost interest.

To determine if this behavior was intended to locate or retrieve prey, a neonatal mouse was held by forceps just outside the gap of the male's terrarium, visible to the lizard. Once the monitor noticed the mouse and recognized its scent, it immediately extended its left forearm through the gap, and began reaching and clawing at the mouse with its forehand. These efforts appeared frantic and were noticeably more coordinated than earlier attempts when a prey item was not present. After keeping the mouse out of reach for several unsuccessful retrieval attempts, it was moved within reach of the monitor. The *Varanus beccarii* hooked the prey with its claws using a grasping forehand movement, then quickly pulled it back into the enclosure where it was seized from the claws with the jaws and swallowed. Additional trials were successfully repeated with both the male and female (through a gap created by partially-opening the female's terrarium door), as well as with *Zophobas morio* larvae offered as prey (Fig. 1).

It is important to note that these reaching and grasping forearm movements involved highly coordinated wrist and digit manipulations (Fig. 1). A similar reaching behavior was observed at the base of the male's terrarium door whenever *Zophobas morio* larvae would fall into a 7 mm wide, 30 mm deep channel running along the length of the door (56 cm) between the door, frame, and weather stripping. Alternating use of both forelimbs, the male was able to retrieve the prey by inserting its forearm into this groove then using a series of side-swiping arm movements until the prey became snagged on a claw or was able to be pulled upwards and out of the opening.

Semi-natural experiments.—Following these initial trials and observations, a simple experiment was carried out to test the use of this behavior in a semi-natural situation. A series of four holes narrower than the width of the monitors' heads measuring 15 x 35, 15 x 65, 20 x 35, and 20 x 65 mm (width x depth) was drilled into one vertically-oriented and one horizontally-oriented tree trunk (trunks ca. 15 cm in diameter) in each terrarium. A variety of prey items, including *Zophobas morio* and *Achroia grisella* larvae,

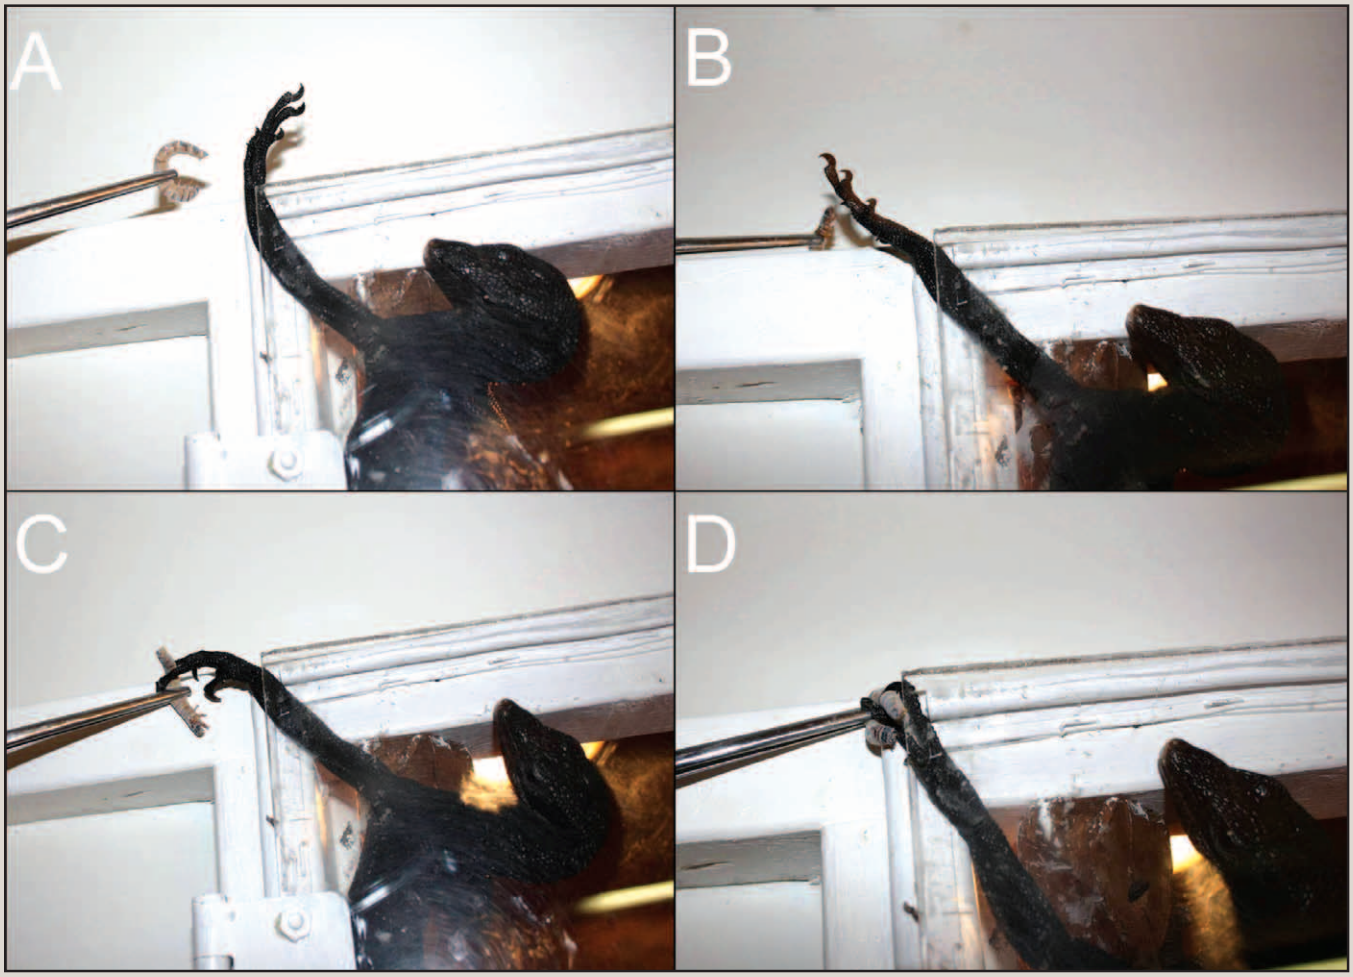

FIG. 1. Male *Varanus beccarii* using reaching arm movements to retrieve a *Zophobas morio* larva through a gap in the terrarium door. A) The forearm is extended through the opening, with the wrist angled back and the digits close together; B) the forearm reaches its furthest extension, with the wrist angled downward and the digits spread apart; C) contact is made with the prey item, and the digits are curled around the prey; D) the prey is pulled through the opening with the claws to be seized with jaws and swallowed.

neonatal mice, and *Acheta domesticus* were placed inside these holes during feedings to test whether each *V. beccarii* specimen was capable and willing to use its forelimbs to retrieve the prey.

Using coordinated forearm movements, both *V. beccarii* successfully retrieved all prey types from all four holes located in each tree trunk. Both individuals used identical extraction behaviors, including the same body positioning, reaching arm movements, and sequences of movements.

Prey is extracted from the holes in vertically-oriented trunks when the monitors are positioned either upright or inverted on the trunk. Once a prey item is detected in a hole either by sight (prey was seen as it was placed inside the hole) or smell, the monitor carefully inspects the hole with a series of tongue-flicks. After unsuccessfully attempting to enter the hole with its head, the forearm is skillfully inserted into the opening, all while maintaining eye contact with the prey inside (Fig. 2). The prey is then either flushed from the hole or pulled out with the foreclaws, where it is seized with the jaws and swallowed. The same behaviors are used on horizontally-oriented trunks (Fig. 3), though when extracting prey, the monitor must lift the prey upwards and out of the hole, requiring slightly different muscular movements and greater coordination, which appeared to take more concentration and effort than with holes in vertically-oriented trunks. Occasionally, prey items are impaled and extracted from the opening while still attached to the claws, where they are then seized with the jaws and swallowed. Both individuals regularly switch usage of each forelimb to maximize its depth of penetration into the hole, depending on its body positioning at the time.

Additional specimens.—Once this behavior was observed in both *Varanus beccarii* specimens in RWM's collection, another keeper of the species was asked to test for the usage of this behavior in an additional adult female (265 mm SVL). When offered mice through a small (ca. 13 mm) opening in the terrarium door, the monitor repeatedly used the same reaching forearm movements described herein to successfully retrieve the prey (S. Sweet, pers. comm.). Likewise, this female also used its forearms to successfully extract mouse parts from a 15 mm x 70 mm deep hole drilled into a 15 cm thick, diagonally-oriented tree trunk (Fig. 4).

DISCUSSION

Initial remarks.—Extractive foraging, the location and retrieval of food items from embedded matrices (Gibson 1986), is rarely performed by non-avian reptiles, limited mostly to

monitor lizards (e.g., Eidenmüller 1993; Gaulke 1989; Sweet 2007). Similarly, skilled forelimb movements such as the ability to reach for and grasp food items are well-documented in a number of mammalian groups (Iwaniuk and Whishaw 2000), but few reptiles have the processing skills, motor coordination, and dexterity needed to perform such movements. As far as we can determine, this report is the first description of a reptile using coordinated forelimb movements to extract prey from narrow and otherwise inaccessible holes in trees. Often associated with primates (e.g., Erickson 1994), tree hole prey extraction provides further support for the idea that monitors share many biological similarities with mammals (e.g., Wood et al. 1977; see also Horn and Visser 1997; Sweet and Pianka 2007). Moreover, it specifically highlights the problem-solving abilities and behavioral complexity of *Varanus beccarii*, thereby supporting Greene's (2004) earlier statements regarding further behavioral specializations in the *V. prasinus* complex.

Is forelimb-assisted extractive foraging learned or genetically-fixed?—Given its apparent rarity among reptiles, the origin of this foraging behavior in *Varanus beccarii*– whether independently learned through insight, genetically-fixed, or some combination of the two, is of particular interest. Extracting food from embedded matrices often requires complex problem solving skills (Gibson 1986). Monitors do not typically rely on extractive foraging because most prey is captured out in the open by dashing forward and seizing it with the jaws. If successful, and if the prey is of sufficient size, it is immediately swallowed. However, in cases of embedded prey, the situation is complicated by the monitor's inability to use conventional prey capture techniques. Unable to insert its head into a narrow opening to seize a prey item, the monitor must devise an alternate capture strategy otherwise the feeding opportunity may be lost. Here, in the case of *V. beccarii*, a conscious decision derived through insight is made to abandon use of the jaws and switch to an alternate technique that utilizes a completely different set of motor skills. The ambidexterity of *V. beccarii* while performing this behavior also exemplifies keen insight given that switching usage between forelimbs represents a foresighted decision that will enable the monitor to reach deeper into a hole, thereby increasing its foraging effectiveness.

Unlike the decision-making component of this behavior, we suspect that the skilled forelimb movements used by *Varanus beccarii* to extract prey are instinctive, rather than individually learned through insight. Because all three *V. beccarii* tested in the present study used the same reaching forelimb movements and body positioning while performing the behavior, and were capable of using them in different experimental situations, the most parsimonious explanation for these consistencies is that the movements have a genetic basis. Alternately, if the limb movements were independently learned, we would expect to have seen some individual variation in body positioning and the performance of this behavior.

Based on these interpretations, we consider forelimb-assisted extractive foraging in *Varanus beccarii* to be a mutual interaction between insight learning and instinct, and therefore expect it to occur in wild populations. However, the ability to learn and successfully perform this behavior might vary from individual to individual since monitors differ greatly in their intellectual abilities (Lederer 1933, 1942). Loop (1976) demonstrated that monitors are gifted with excellent memories, and can remember trained, food-oriented procedures even after several weeks of latency. Therefore, once learned by an individual and added to its behavioral repertoire, extractive foraging is unlikely to be forgotten if it reliably produces feeding opportunities.

Requisites for use in the wild.—If forelimb-assisted extractive foraging is to be a useful strategy for *Varanus beccarii* in the wild, we contend that several conditions must be met. First, *V. beccarii* would have to be an arboreal forager that feeds on tree-dwelling prey, and second, it must forage in environments where both arboreal prey and tree holes are abundant and accessible.

Scientific observations on the natural history of *V. beccarii* in the Aru Islands, Indonesia are lacking despite frequent collection for the live reptile trade (Pernetta 2009), and all that has been published on its occurrence to date appears to have originated through second-hand sources. Bennett (1995, 1998) reported that *V. beccarii* occurs in mangrove swamps whereas Sprackland (2009) claims that it inhabits lowland wet forests and swamps. Like all other members of the *V. prasinus* complex, *V. beccarii* is indeed highly specialized morphologically for an arboreal lifestyle (Greene 1986, 2004), and behavioral observations of *V. beccarii* in captivity further suggest that it is a skilled tree-dweller (Hartdegen et al. 1999, 2000; Krebs, pers. comm; pers. obs.).

Dietary studies indicate that members of the *Varanus prasinus* complex feed predominantly on arboreal arthropods (Greene 1986; Irwin 1994). Though not recovered from the single *V. beccarii* stomach analyzed by Greene (1986), we suspect that the soft-bodied larvae of some wood-boring beetles and bark-dwelling caterpillars may make appropriate prey items for this particular foraging behavior in the wild. During experimental

trials, soft-bodied prey such as neonatal mice and *Achroia grisella* larvae (but also more rigidly-bodied prey such as *Zophobas morio* larvae and *Nauphoeta cinerea*) were easily extracted from tree holes when impaled by the claws. The sharp foreclaws and reaching forearm movements of *V. beccarii* may also be useful for retrieving nocturnal geckos, tree frogs, and insects that seek refuge in tree holes and crevices by day.

When compared to other monitor lizards, members of the *Varanus prasinus* complex may possess the longest and slenderest forelimbs in relation to body size (compare drawings by Bellairs 1969). The long and slender forelimbs and elongated digits of *V. beccarii* clearly compliment tree hole extractive foraging well, and allow individuals to deeply penetrate narrow openings all the way up to the shoulder. This ability should enable *V. beccarii* to exploit an ecological niche that may not be utilized by many other predators within its range, and can potentially diversify the number of different prey items taken, maximizing the total number of foraging opportunities.

Comparisons of arboreal foraging in Varanus.—Limited observations on arboreal species in the field prevent a thorough analysis of tree hole foraging tactics used by monitors. However, field observations on the foraging habits of *Varanus glauerti* in northern Australia (Sweet 1999) enable direct comparisons between *V. beccarii* and this similar-sized arboreal species. Like *V. beccarii*, *V. glauerti* will also seek out hidden prey within holes and crevices in trees (Sweet 1999); however, the strategies employed by each to retrieve prey from narrow openings are markedly different. Once a prey item is discovered inside a tree hole that is too small to enter with the head, *V. glauerti* will attempt to widen the diameter of the opening by clawing at it margins until it is large enough for the head to enter, where the prey can then be seized with the jaws (Sweet 1999). Although captive *V. beccarii* will also enter holes to subdue prey if large enough for the head (pers. obs.), its use of the forelimbs to extract prey from smaller openings rather than attempting to widen them, distinguishes it behaviorally from *V. glauerti* as well as all other monitor lizards, as currently understood.

Forelimb-assisted prey extraction in additional taxa?—Given that several monitor species occur in forested environments and might have arboreal habits and diets similar to those of *Varanus beccarii*, it is possible that forelimb-assisted extractive foraging might be used by additional taxa. Given their relatedness, and the near-identical similarities in size, morphology, diet, and arboreality between *V. beccarii* and other members of the *V. prasinus* complex (Greene 1986; Sprackland 1991; Ziegler et al. 2007), we suspect that this behavior is also used by other members of the complex. Notably, Irwin (1996) reported seeing a wild *V. keithhornei,* sister taxon to *V. beccarii* (Ziegler et al. 2007), "on the ground scratching with its forefeet in a rotting log, obviously foraging for food." Whether this observation refers to the same prey extraction behavior reported here for *V. beccarii* is unclear; however, it necessitates the need for further investigation of forelimb-assisted extractive foraging in the *V. prasinus* complex.

It might seem obvious that the skilled forelimb movements described here for *Varanus beccarii* represent a specific behavioral adaptation for use in trees. However, we cannot rule out the possibility that this foraging behavior might also occur in terrestrial species. The ability to extract prey from rock crevices, tree stumps and felled trunks, burrows, and other narrow openings would benefit the foraging efficiency of terrestrial monitors. Indeed, some terrestrial species have developed unique and insightful methods of extracting prey from rock crevices and burrows using coordinated tail movements (Eidenmüller 1993; Gaulke 1989; Horn 1999). Use of the forelimbs in similar situations can be equally useful for extracting prey, and is perhaps more feasible from a developmental standpoint given that many species are known to use the forelimbs in various capacities while foraging (e.g., Auffenberg 1981, 1988, 1994; Blamires 2004) or handling and fragmenting prey (e.g., Auffenberg 1981; Hartdegen et al. 2000; Horn 1999; Kiehlmann 1999; Krebs 1979, 2007, pers. comm.; Stanner 2010).

Implications for future research.—Arboreal species offer unique opportunities for studying the insight and behavioral complexity of monitors, particularly because they inhabit complex, three-dimensional environments (Greene 2004) and may require more advanced processing skills and finer motor coordination than comparatively-sized terrestrial species. Studies on several mammalian groups have shown that brain sizes are positively correlated with arboreality (Budeau and Verts 1986; Eisenberg and Wilson 1981; Meier 1983). Because monitors vary considerably in habit from strictly terrestrial to largely arboreal, and share many ecological and physiological affinities with mammals (Wood et al. 1977; Horn and Visser 1997; Sweet and Pianka 2007), it is of interest whether selective pressures have favored a similar evolutionary trend in monitors. Surprisingly, the only direct study to compare relative brain sizes in monitors focused solely on the ecologically-dissimilar *Varanus salvator* complex and *V. glebopalma*, but did note distinct morphological differences between the two (Andres et al. 1999). Similar comparative studies on monitor brain sizes which sample a greater diversity of taxa can provide a framework for understanding the evolution of encephalization and intelligence within the genus.

Further investigations of skilled forelimb movements and extractive foraging in monitor lizards are planned. When applied to current phylogenies (Ast 2001; Fitch et al. 2006; Ziegler et al. 2007), confirmed usage of this behavior by additional taxa can allude to the evolution of skilled forelimb movements in monitor lizards, but more broadly in tetrapods as well (Iwaniuk and Whishaw 2000). Additionally, observations of forelimb-assisted extractive foraging in the field can yield important details about its usage and importance to wild monitor populations which cannot be inferred from captivity.

Finally, our observations have important implications for the management of *Varanus beccarii* in captivity. Given the importance of enrichment stimuli in the husbandry of monitor lizards (Burghardt et al. 2002; Manrod et al. 2008; Sunter 2008), replicating or modifying the drilled tree trunks described in this report and using them during feedings can provide a valuable source of behavioral enrichment for captive individuals. All specimens tested in the present study continue to show interest in the drilled tree trunks within their terraria, stopping to investigate holes and crevices as they are encountered through daily foraging activity. Such an apparatus can potentially increase activity, reduce boredom and stereotypic behaviors, and improve the overall quality of life for specimens of *V. beccarii* and possibly other members of the *V. prasinus* complex maintained in zoos and other captive situations.

We welcome correspondence and encourage feedback from zoos, researchers, and private keepers working with monitor lizards on the subjects of extractive foraging and skilled forelimb movements, as well as additional behavioral specializations in *Varanus*.

Acknowledgments.—We thank Sam Sweet for testing his captive specimen and for sharing observations and photographs. We also appreciate helpful discussions and constructive comments on earlier drafts of this manuscript by Uwe Krebs, Michael Cota, and two reviewers.

Urban Students and Urban Serpents: The Effects of Hands-on Learning in Student Perception of Snakes

Snakes and teenagers share a common negative stereotype and are often maligned or feared because of this reputation. Here, I present observations and an analysis of shifts in high school students' perceptions of snakes after completing an intensive eight-week course, including participation in field studies of urban garter snakes. These observations support the inclusion of such experiential and in-depth programs in schools as means both to teach science and foster understanding and appreciation of the natural world. Programs providing such opportunity can work to reverse negative public image of both snakes and teens.

The involvement of non-scientists in scientific studies and conservation efforts has recently gained attention as a valuable, and even integral, component of such projects (Cooper et al. 2007). Wildlife education, specifically those programs which effect attitudinal change, can provide great benefit to conservation efforts and are much needed (Adams and Thomas 1986; Mitchell and Jung Brown 2008; Wojnowski 2009). Attitudinal changes toward nature are most effective when they result from an increase in factual knowledge of the natural world, which in turn can lead to a more full participation in democratic society (Hendee 1972), a goal at the core of public education. Additionally, Morgan and Gramann (1989) found that the most effective strategy to increase knowledge and improve attitudes toward snakes is a "full-treatment" approach, combining information-based and experiential activities. Such programs in a variety of subject areas provide a depth of understanding that promotes the possibility for positive shifts in attitudes and actions (Hooks 1994). Examples that have successfully integrated education and conservation can be found from Kenya (Wojnowski 2009) to Texas (Sosa et al. 2010). Such efforts work toward the goals of both collecting scientific data and developing public empathy toward native herpetofauna that are likely to be incidentally encountered by community members.

Snake mythology permeates our culture, often leading to undue fear and misunderstanding (Gibbons 1983). Public education about snakes and the roles they play in a variety of ecosystems is lacking (Wojnowski 2009) and, when it does occur, is often conducted by those without proper knowledge themselves (Gibbons 1983). Recent studies have even postulated that the human fear of snakes has an evolutionary basis and is not affected by direct experience (LoBue and DeLoache 2008). This analysis presents evidence to the contrary: that perception of snakes can shift as a result of educational experiences. Specifically, hands-on involvement of non-scientists in herpetological studies serves to increase both empathy and understanding, as well as benefits the collection of scientific data.

Materials and Methods.—From August to October 2010, I taught an interdisciplinary and hands-on class, "Snakes & Letters," at P.S. 1 Charter School in Denver, Colorado, USA. The eight-week class included curriculum in both science and English and was attended by 28 high school students (age range: 13–19 yrs), though not all students participated for the duration. The school is racially diverse, with 85% of students categorized as "high-risk" for not completing high school, as defined by Colorado law (Colorado General Assembly 2010). Students engaged in lectures, discussions, readings, demonstrations, and hands-on activities to develop their skills in the areas of scientific knowledge, use of scientific equipment, experimental design,

FIG. 1. Students from P.S. 1 Charter School display the garter snakes they are studying at sites in Denver, Colorado, August to October 2010.

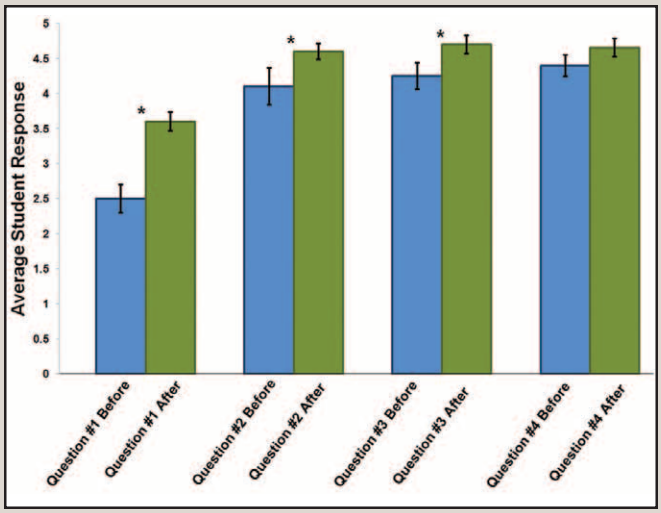

FIG. 2. Average student responses to questions in pre- and post-class questionnaires. Question #1: "How much do you know about snakes?" (1 = "I don't know anything" to 5 = "I'm an expert"); Question #2: "Are snakes an important part of nature?" (1 = "Snakes don't matter at all" to 5 = "Snakes are very important"); Question #3: "Should snakes be protected?" (1 = "Snakes should never be protected" to 5 = "Snakes should definitely be protected"); Question #4: "What is your attitude toward snakes?" (1 = "I can't stand snakes" to 5 = "I love snakes"). Error bars represent one standard error. Statistically significant changes ($p < 0.05$) denoted with an asterisk.

and writing. Students watched a presentation by a visiting biologist and photographer and visited the venomous snake laboratory at the University of Northern Colorado. Two live snakes were incorporated repeatedly into class activities and often handled by students, a Corn Snake (*Elaphe guttata*) and a Sonoran Mountain King Snake (*Lampropeltis pyromelana*). Additionally, there were eight extended outings in which students visited urban sites and participated in field studies of the Western Terrestrial Garter Snake (*Thamnophis elegans*) and Plains Garter Snake (*T. radix*) designed to better understand the impact of urbanization on these species (Fig. 1).

Snakes were located by broad-area visual survey, conducted by myself and the students, and hand captured. Because of variability in site size, student attendance, and scheduling constraints, surveys were conducted by fortuitous encounter and not standardized. Students participated in observing and recording data, including habitat description, weather, length, mass, and GPS-based locality and movement data. After processing, all snakes were released at the point of capture. The four sites visited are situated along a gradient of size, urbanization, and anthropogenic impact: a 10-ha downtown city park, a 20-ha unimproved watershed (12.0 km from downtown), a 50-ha nature preserve (13.7 km from downtown), and a 1050-ha suburban city park (31.2 km from downtown). While participating in these field studies, students encountered 14 live and two dead garter snakes and one live Racer (*Coluber constrictor*). Data were collected for all snake encounters, with one exception due to communication failure and release by students before measurements could be taken.

On the first and last days of the class, students completed identical written questionnaires, largely modeled after those of Sosa et al. (2010). These questionnaires included two primary sections, analyzed here. The first section involved four self-assessment questions, answered on a scale of 1–5, measuring student knowledge and empathy. The second section contained a list of twelve adjectives, which students circled if they believed to be an apt descriptor of snakes. Before and after results were compared using a paired t-test with a level of significance $\alpha = 0.05$ (Triola 2008).

Results.—Because of variable attendance and course changes, twenty students participated in the full curriculum and completed both the pre- and post-questionnaires. In the first section, students were asked to rank their response to questions on a gradient of 1–5, with the attitudinal equivalent of the low and high values given. Students showed a significant increase in self-assessed knowledge or empathy in the following questions: "How much do you know about snakes?" (1 = "I don't know anything" to 5 = "I'm an expert") ($p < 0.0001$); "Are snakes an important part of nature?" (1 = "Snakes don't matter at all" to 5 = "Snakes are very important") ($p = 0.0375$); and "Should snakes be protected?" (1 = "Snakes should never be protected" to 5 = "Snakes should definitely be protected") ($p = 0.046$). An increase, though not statistically significant, was found in response to the question "What is your attitude toward snakes?" (1 = "I can't stand snakes" to 5 = "I love snakes") ($p = 0.2$) (Fig. 2).

Statistically significant increases were found in students' use of the adjectives "strong" ($p = 0.005$) and "curious" ($p = 0.003$) and increases, though not statistically significant, were also found in their use of the adjectives "smooth" ($p = 0.56$), "boring" ($p = 0.33$), "mysterious" ($p = 0.49$), "angry" ($p = 0.3$), "cute" ($p = 0.21$) and "friendly" ($p = 0.16$). A statistically significant decrease was found in the use of the adjective "dangerous" ($p = 0.0021$) and decreases, though not statistically significant, were found in their use of the adjectives "slimy" ($p = 0.2$) and "scary" ($p = 0.6$) (Table 1).

Discussion.—The results of these questionnaires demonstrate an increase in student understanding of and empathy toward snakes, as shown by changes in student self-assessment and by the increased use of the positive descriptors "strong" and "curious" and a decrease in the use of the negative descriptor "dangerous." The students' belief that their knowledge increased was confirmed by classroom assessments, including quizzes, presentations, and written papers. Interestingly, the one survey question in the first section for which no significant increase was found ("What is your attitude toward snakes?") was also the question that received the highest average score in the pre-class questionnaire. Generally speaking, students chose this class over

TABLE 1. Number of students selecting adjectives to describe snakes in pre- and post-class questionnaires. Statistically significant changes ($p < 0.05$) denoted with an asterisk.

Adjective	# of students selecting before class	# of students selecting after class	Change
Slimy	4	1	-3
Cute	7	11	+4
Smooth	16	17	+1
Strong	12	19	+7*
Boring	0	1	+1
Curious	6	16	+10*
Mysterious	13	15	+2
Dangerous	15	7	-8*
Friendly	12	16	+4
Angry	0	1	+1
Scary	2	1	-1

four other such interdisciplinary project classes at the beginning of the term. It would be most revealing to conduct a similar study with students who were not self-selecting into a class explicitly studying snakes. Additionally, curriculum examining invasive snake species and their impact would offer students a more complex and realistic understanding of snake ecology.

These results support the claim of Hendee (1972) that an increase in knowledge can lead to a shift in attitude as well as the findings of Morgan and Gramann (1989) that wildlife education combining the presentation of information and hands-on experiences is effective in increasing student knowledge and improving attitudes toward snakes. Unlike these previous studies, however, this was a much longer course in which students experienced snakes in their natural habitat.

Scientific research can benefit from such student involvement in a variety of ways. The number of potential snake captures is positively related to the number of searchers; more snakes were captured with students than would have been captured otherwise. Additionally, these students' experience and knowledge make them better-suited for participation in citizen-science programs and more aware of the workings of local ecosystems. Even after the class had ended, students continued to inform me of other urban snake sightings. Moreover, students who are exposed to positive experiences in a particular field are more likely to pursue that path in their future education.

That such a class increases student knowledge should not come as a surprise; such an increase is a fundamental objective of science classes. In order for such knowledge to become an active part of students' lives, a concomitant increase in empathy must also occur. This affinity, developed through personal experiences, can allow students to recognize applications of classroom material to their world and communities and to develop a personal interest in such topics, which in turn can serve their academic development (Hooks 1994). Attitudinal changes are especially valuable in terms of urban and suburban conservation, where public perception and participation are integral to the success of many programs (Cooper et al. 2007). An educational program such as this, which combines traditional classroom techniques with hands-on experiential learning, can be successful in increasing student knowledge of the natural world, empathy for the organisms with which they share ecosystems, and confidence in their ability to understand both.

Acknowledgments.—Many thanks to the P.S. 1 students who showed great curiosity and enthusiasm; to Principal Laura Laffoon for promoting such experiences and Elaine Scheffler for her enthusiasm and dedication to teaching; to Bluff Lake Nature Center, Bear Creek Lake Park, Denver Parks & Recreation, and Lowry Redevelopment Authority for allowing us to conduct studies on their land; to Stephen Mackessy of the University of Northern Colorado and David Herasimtschuk for generously sharing their expertise and time; and thank you to Colorado Reptile Humane Society for allowing us to foster a snake in our classroom. This manuscript was improved significantly after contributions from two anonymous reviewers. All research was conducted under Colorado Division of Wildlife Collection Permit 10HP939.

Status and Distribution of the Rim Rock Crowned Snake, *Tantilla oolitica*

KIRSTEN N. HINES
260 Crandon Blvd, Ste 32 #190
Key Biscayne, Florida 33149, USA
e-mail: Kirsten.N.Hines@gmail.com

The Rim Rock Crowned Snake (*Tantilla oolitica;* Telford 1966) is one of three species of small, burrowing snakes of the genus *Tantilla* found in Florida, USA. Restricted to extreme southeastern Florida, its range traditionally has been defined as the east coast of Miami-Dade Co. extending south to the Middle Florida Keys of Monroe Co., with its presence in the Lower Keys remaining uncertain (Campbell and Moler 1992). This area is highly developed and the rockland habitats this species has historically depended upon have been reduced to less than half their original extent (Enge et al. 2003; Snyder et al. 1990). In addition to its restricted range, this species is elusive and only 35 individuals were officially recorded as of 2004 (Scott 2004). *Tantilla oolitica* has been on the State of Florida's Threatened Species list since 1975, yet there have been no dedicated range-wide field surveys for the species. Given the species' increasingly limited habitat and apparently small population, a better understanding of its status and options for its conservation are needed.

Here I report the results of an extensive and intensive range-wide survey for *T. oolitica* between 2007 and 2010. In addition to survey work, I conducted extensive reviews of the literature and museum records and undertook wide-ranging personal interviews. My goal was to create a comprehensive understanding of *T. oolitica*'s distribution and current status to suggest conservation implications for this species.

Methods.—I conducted the study from 2007 to 2010 in southeastern Florida from northern Miami-Dade Co. through the Florida Keys to Key West. The study area covers all of the historical and potential habitat for the species. I concentrated on

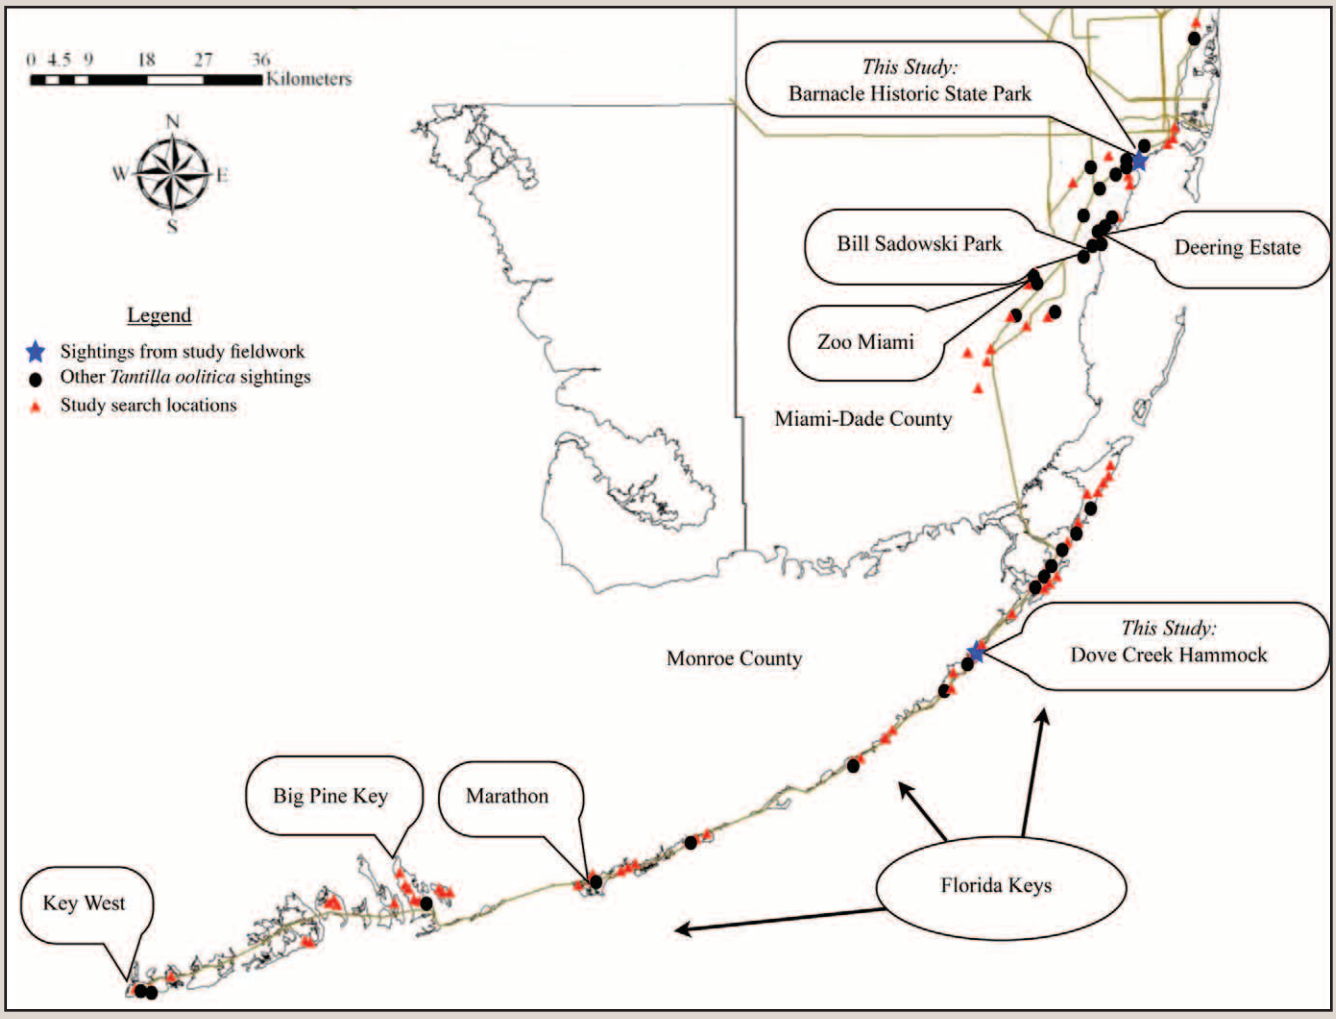

FIG. 1. Range of *Tantilla oolitica*, including all sightings from 1934–2010 and all locations searched during this study.

protected areas (parks, refuges, etc.) and occasionally private properties containing appropriate habitat—forests and pinewoods on a limestone substrate (Snyder et al. 1990), referred to locally as rockland hammocks and pine rocklands (FNAI 2010). From 2007 to 2008, I focused on the core of the historical range from downtown Miami to Marathon in the Middle Keys. Thereafter, I concentrated on the edges of the range, exploring the northern and western boundaries of the species in Miami-Dade Co. and potential habitat in the Lower Keys.

I conducted the survey using cover board arrays and concentrated searches. Cover board searches consisted of 1–3 arrays in each of 12 protected areas for a total of 28 arrays. Each array consisted of three 0.6 x 1.2 m pieces of 1.3 cm-thick plywood placed within a few meters of one another. I placed the boards in March 2007 and examined them every 1–2 months from May 2007 to April 2008, with one final check in August 2009. I thoroughly searched all leaf litter under the cover boards at each visit. I conducted monthly concentrated searches between May 2007 and April 2008 with additional, less frequent searches continuing through October 2010. Searches consisted of all participants spreading out within an area and systematically searching beneath all moveable rocks, logs, and other cover items. I recorded a GPS location at the start of each survey period and recorded time at the start and end of the search to standardize findings by search effort (person-hours). With few exceptions, I conducted concentrated searches in the protected areas containing cover board arrays on every visit between May 2007 and April 2008. During this period, I also searched other privately and publicly owned areas containing appropriate habitat within this core area as permission was granted. I searched protected areas and private lands at the edges of *T. oolitca*'s historical range from 2009 to 2010.

I made information requests for *T. oolitica* records and findings at museums with known *T. oolitica* holdings, Florida Natural Areas Inventory (FNAI), and the "Field Herp Forum" (www.fieldherpforum.com). In addition, I contacted 102 researchers, resource managers, hobbyists and others who might encounter *T. oolitica* for information on potential sightings. I compiled and mapped all sighting information gathered from reliable sources.

Results.—Cover boards were in the field for 880 days of sampling. I checked each of the 84 boards at least eight times during this period, with the 30 boards in Miami-Dade Co. being checked nine times. *Tantilla oolitica* was not found under any of the placed cover boards. A total of 393.4 person-hours were spent in concentrated searching for *T. oolitica* at 57 locations between north Miami-Dade Co. and Key West at the south end of Monroe Co. (Fig. 1). These searches yielded two *T. oolitica* sightings (Fig. 1). I saw one at the Barnacle Historic State Park in Coconut Grove (25.7259°N, 80.2434°W) on 8 May 2007 at 0845 h. This snake was discovered in hammock habitat in a loose pile of rock and moist, dark soil about 15 cm beneath the surface. The second *T. oolitica* was discovered during concentrated searches by Michael Rochford at 0950 h on 25 May 2007 at Dove Creek Hammock in Key Largo (25.0322°N, 80.5018°W) (Fig. 2). This individual was in hammock habitat coiled less than 10 cm beneath a rotting board in moist, dark soil. During the study period, three additional sightings were reported. Opportunistic sightings occurred on Big Pine Key in 2007 (Yirka et al. 2010) and Key West in 2009 (R. Sterling, pers. comm.). Zoo Miami staff caught an individual in a pitfall trap at one of their pine rockland drift fence arrays in 2009 (D. Smith, pers. comm.).

Information requests yielded reports of 49 *T. oolitica* sightings between 1934 and 2010 (Table 1). Sources included 23 museum specimens, 3 FNAI records, and personal accounts from 17 individuals. Seventy-five percent of the people interviewed reported no *T. oolitica* sightings. Most interviewees who had seen *T. oolitica* reported one or two sightings of separate snakes with four being the maximum. There was only one, unprecedented, report of more than four observations by one person. Glenn Fried, former naturalist at Bill Sadowski Park (25.6045°N, 80.3217°W) and the Deering Estate (25.6130°N, 80.3091°W), reported observing at least 33 individuals at those parks and a nearby abandoned lot (25.6078°N, 80.3114°W) between 1983 and 1998, including sightings of more than one snake at a time and repeated sightings of individuals. Given that these observations are so deviant from any others and are unsupported by documentation, I have included the sighting locations but have limited the counts to one per location.

The overall distribution of *T. oolitica* as documented in this study is shown in Fig. 1. Thirty-two site locations from North Miami to Key West suggest the extent of present distribution. Within this range, *T. oolitica* is found both within its historical rockland habitats (16 sightings in hammock, pine rockland, or hammock ecotone; Table 1) and disturbed areas (19 sightings from roadsides, vacant lots, or open fields; Table 1).

Discussion.—This study increases the number of *T. oolitica* reports since the Scott (2004) account from 35 to 49 and

*Unkown number of sightings (see explanation in Results section)

confirms that the species range extends through the entire Florida Keys, matching the distribution of rockland hammock and surrounding pine rocklands. Historically, these habitats, supported by the relatively high ground of the limestone ridge (Lodge 2010), represented the only areas protected from flooding during the wet season. Drainage has created additional dry lands, but there is no evidence of *T. oolitica* leaving the rockland habitat footprint to inhabit previously submerged habitats, such as former marsh. Instead, as its scientific name suggests, much of the distribution of this species coincides with oolitic limestone (Miami Limestone) found in Miami-Dade Co. and the lower portions of the Florida Keys in Monroe Co. It also occurs on the Key Largo Limestone substrate found in the upper Florida Keys (Hoffmeister 1974; Randazzo and Halley 1997). Within Miami-Dade Co. it is restricted to the modestly elevated, narrow outcropping of limestone called the Miami Rock Ridge, which historically was a narrow peninsula of upland bordered by Biscayne Bay to the east and the Everglades to the west, but now is home to metropolitan Miami.

It is difficult to assess population size of *T. oolitica* because the species is not only rare, but elusive. Many Florida herpetologists (researchers and hobbyists) have never seen one despite their attempts to do so. A study by Enge et al. (2004) targeting *T. oolitica* in six Miami-Dade Co. parks failed to find any. Staff at Zoo Miami began reptile surveys with coverboards and drift fence arrays with pitfall traps in 2005. They expanded their trapping efforts in 2007 to specifically search for *T. oolitica* (S. Conners, pers. comm.). In all this effort, they found one *T. oolitica* in a pitfall trap in August 2009 (D. Smith, pers. comm.). In my study, 84 coverboards and over 393 person-hours of searching over a three-year period yielded only two *T. oolitica* sightings. Even on the Field Herp Forum, a venue for some of the most avid and successful field herpetologists, *T. oolitica* is one of the species most commonly lamented as lacking in South Florida reptile life lists. The success rate in finding *T. oolitica* is both historically and currently low, making population size estimates virtually impossible. Looking at observation rates instead, there is an indication of population stability since the numbers of sightings in the last ten years are comparable with those in previous decades. However, we have no way of verifying this population trend and a lack of repeated observations at any given location leaves room for concern.

Sites at and around Bill Sadowski Park in Miami and in Marathon of the Florida Keys yielded multiple sightings in the past. This trend seems to have stopped despite recent efforts to uncover this species. Some areas have been lost to development, but even protected Bill Sadowski Park has failed to yield sightings in almost 20 years after affording three over a ten-year period in the 1980s to 1990s. I placed nine coverboards at this park and spent 25.3 person-hours searching the property, but found nothing. Repeated sightings are admittedly the exception rather than the rule for this species, but many of the people I interviewed speculated that *T. oolitica* was not being seen, particularly in these areas of repeated sightings, because people were not looking for them. My study suggests otherwise. It was designed as a mark-recapture study, but that component never came to fruition because I never observed *T. oolitica* more than once at any given location despite repeated efforts. Although these results are insufficient for making population estimates, they do highlight the rarity of the species.

While much remains unknown about *T. oolitica*, it is clear that the species faces many threats. Less than 2% of the historical pine rocklands on the Miami Rock Ridge currently remain, and hardwood hammocks both in Miami-Dade Co. and throughout the Florida Keys have been reduced to less than half their original extent (Enge et al. 2003; Snyder et al. 1990). Fragmentation eliminates immigration between patches, and in an urban setting inevitably translates into road

fatalities (Table 1). However, *T. oolitica* does seem able to persist within remaining fragments. Conservation requires protection of these fragments, which is generally the case in Miami-Dade Co., but not in the Florida Keys where development and saltwater intrusion associated with sea level rise continue (Ross et al. 1994; USFWS 1999). Proper management of habitat fragments for *T. oolitica* includes protection from non-native species, illegal dumping and altered fire and hydrology patterns (USFWS 1999), the latter likely being the most critical. South Florida's water table has dropped by as much 1.2 m in areas (Sklar et al. 2002), creating drier rockland habitats than historic conditions (USFWS 1999). Centipedes, probably the main food source for *T. oolitica* (Campbell and Moler 1992; Todd et al. 2008), require moist conditions (Koehler and Oi 2003). Patch management must involve rehydration.

Tantilla oolitica is currently listed as Threatened by the State of Florida (FWC 2010) and as Endangered by the International Union for Conservation of Nature (IUCN) Red List (Hammerson 2007) based on restricted range and loss of habitat. This study confirms the appropriateness of these designations. The species also merits protection under the Federal Endangered Species Act, under the provisions for "the present or threatened destruction, modification, or curtailment of its habitat or range" and "the natural or manmade factors affecting its survival" (USFWS 2010).

Because of its scattered distribution across landscapes managed by diverse entities, a formal comprehensive conservation plan is needed. The plan's components, in addition to patch management, should include monitoring on all sites where it occurs (utilizing a combination of concentrated searches, coverboard arrays, and drift fences with pitfall traps), an educational campaign to increase public awareness, an official information repository, a captive breeding population and re-introduction since natural dispersion among patches is no longer viable.

Acknowledgments.—Funding for this research was provided by the U.S. Fish and Wildlife Service and the Zoo Miami Conservation and Research Fund. This project was begun under the auspices of the Institute for Regional Conservation (IRC), which provided additional logistic support, as did the University of Florida. At IRC, I particularly thank Keith Bradley and Patty Castillo-Trenn, for assistance in starting this project. I thank John Iverson for project planning advice, 27 volunteers for field assistance, museum staff and others who provided data, various permitting authorities and site managers who allowed this research, and 102 interviewees, particularly Steve Conners, Jonathon Decker, Glenn Fried, Louis Porras, Dustin Smith, and Randy Sterling. I especially thank Michael Rochford who found one of the snakes included in this study, Dustin Smith who was vital in the continuation and expansion of this project, and James Kushlan for comments on the manuscript.

A New Technique for the Production of Large Numbers of Clay Models for Field Studies of Predation

One of the cornerstones of ecology is the study of interspecific interactions, such as predation, herbivory, and mutualism. Studies of predation have proven to be difficult since actual field observations are often limited. Synthetic prey models have proven to be useful tools for measuring predation attempts, as identical stimuli can be created and used without harming the test organism in question. In addition, replication of a particular prey phenotype is more tenable with models than with real organisms, and allows for careful manipulation of phenotypic traits of interest, such as color and size.

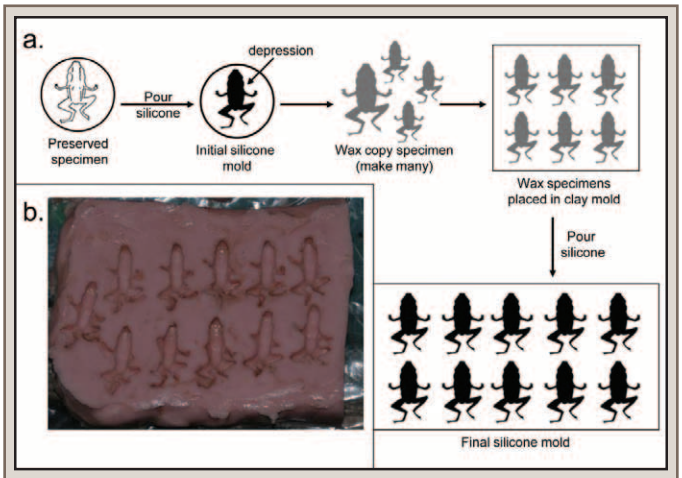

FIG. 1. A) Sequential procedure for making master silicone molds, B) Final silicone master molds.

FIG. 2. Clay well surrounding the preserved specimen.

Although predation can be studied relatively easily in captive settings (e.g., Lindström et al. 2006), studies of predation are more problematic, as they require models that withstand variable habitats and unpredictable weather conditions. Predation on several reptile and amphibian taxa (including snakes [Brodie 1993; Harper and Pfennig 2007], salamanders [Kuchta 2005], and frogs [Saporito 2007; Noonan and Comeault 2009]) has been subject to field research using clay or plasticine models. Similarly, for clay models of prey species that are highly variable in coloration and patterning, high attention to detail is warranted, but the development of highly realistic models is often prohibitively time-consuming or costly. Moreover, recent experiments (Noonan and Comeault 2009) have demonstrated that predation rates are often low, necessitating a large quantity of models to elucidate predation patterns.

We present a novel technique to generate large numbers of life-like models using customizable silicone master molds to produce clay models. Master molds allow for quick development of clay models of varying size and shape, which can subsequently be painted for patterning and coloration studies. Due to the nature of the clay used, marks left by predators can be scored for presence or absence of predation attempts, and in some cases used to identify predator species.

Materials and Methods.—Construction of the models began by taking an initial mold of a preserved specimen of a poison frog, *Ranitomeya imitator*, available from previous research. A small layer of modeling clay (Sculpey) was smoothed onto a small wood board and heated with an alcohol burner to soften it. A preserved frog was then placed into a life-like resting pose and lightly pressed into the clay in a posture similar to a sitting stance (Fig. 1). Although it is possible to make a 3-D mold that includes ventral characteristics, it would involve additional steps unnecessary for our purposes, so the ventral surface of the frog was flattened against the clay.

A well was then constructed around the frog approximately 2 cm high using the same modeling clay (Fig. 2). The clay and specimen were then coated with a Krylon Matte Finish Spray® (Krylon Products Group) to protect the skin of the specimen as well as seal in chemicals that could inhibit the curing process of the silicone. A mold release (Mann Ease Release 200™, Mann Formulated Products) was sprayed over the entire frog and clay bed/wall to allow for easy release of the silicone. The silicone and catalyst (Smooth-Sil 940®, Smooth-on Corp.) were mixed in a 10:1 ratio by weight. This mixture was then poured, from a height of approximately 1 m, into a thin stream in one corner of

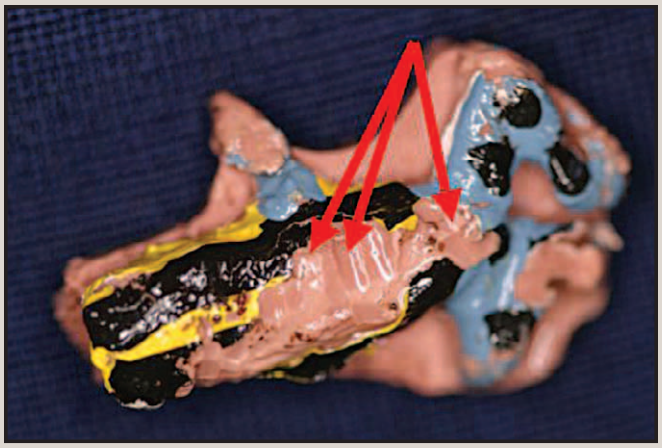

FIG. 4. Model *Ranitomeya imitator* with mammalian incisor marks (arrows depict attacked regions).

the well, allowing it to spread evenly over the specimen. Pouring in a thin stream away from the specimen allows for the spread of the silicone to cover all surfaces and avoids development of air bubbles. The silicone master mold cured in approximately 18 h at which point the preserved frog was extracted and returned to alcohol. Although specimens remain largely intact during creation of molds, damage to skin is likely as a result of the matte finish spray.

Following production of the mold, resin (plastic) forms were poured that were then used for the production of the final silicone production molds, in which the clay models are made (Fig. 3). The resin (Smooth-cast 300®, Smooth-on Corp.) was mixed according to the manufacturer's indications (1:1 by volume) and poured into the silicone voids using the pouring technique described above for the pouring of silicone. Curing time for this step is approximately 30 minutes. Two methods were tested to cure the resin, both curing them in ambient temperature and pressure conditions versus under high pressure. Both yielded similar results. There may be a possible benefit of using increased pressure to avoid air bubble imprints, although these benefits were minimal in our testing. The resin frog models were then spaced on the modeling clay (the same as originally used to make the initial silicone mold), in groups of 10–12 models per mold and the final silicone was mixed and poured. When the resin frogs were removed, the voids were used to pour melted plasteline clay.

To heat the clay we used a small crock-pot on the highest setting to melt no more than half of a two-pound block. The clay was heated in the crock-pot for approximately one hour, or until it was liquefied. Release agents can be added to the silicone prior to pouring clay to facilitate clay extraction, though this is not necessary. While release agents will extend the life of molds, it can also serve as an olfactory attractant to predators.

The clay was spooned onto the molds, tapping it in each form to eliminate air bubbles. An extra 1/4-inch of clay was added and smoothed over the molds to allow for easy separation from the silicone, as well as to strengthen the very thin legs. The tablets of clay then were painted using non-toxic acrylic paints. Alternatively, colored clays could for species with simple color patterns, avoiding the need to paint.

For our uses, we replicated the silicone master mold step 15 times to be able to make roughly 150 models with each heating of the clay block. While it is possible to do much larger master molds, extracting the models from smaller molds is easier as smaller molds allow for release of the clay out of the mold by gentle bending. This allows for finer detail of the models, such as small toes or tail tips, to be retained, with a reduced risk of breaking fragile body parts. When the molds are carefully handled and used in combination with a non-toxic release agent, they can be expected to last several years. We produced nearly 2,000 models with no noticeable detrimental effects to the master molds (Fig. 4).

Discussion.—We provide a novel method for the rapid production of large quantities of detailed models. This method is preferable to other production methods for clay models for several reasons. First, due to the ease of model preparation from master molds, models can be made in even the most remote locations, provided there is a way to melt the clay. Once the resin forms are made they can be used unlimited times to produce silicone master molds, potentially allowing production of thousands of models in a short time. Lastly, for predation studies, accurate models allow for the testing of specific hypotheses of color or specific traits, while partially alleviating concerns that predators will not recognize unrealistic forms. However, we note that investigators should conduct field trials of paint and model formulation prior to deploying models—as an example, we found that some paint formulations were subject to attack by ants in the Neotropics.

The future of clay models is promising with higher attention to detailed realism and faster production times allowing for more rigorous hypothesis testing. Our method provides a way to generate large amounts of accurate clay models with minimal effort.

Acknowledgments.—We thank J. Brown, E. Twomey, T. Kosch, and K. Fieselman for companionship in the field and tolerance of thousands of clay frogs in the house in Peru. We wish to acknowledge model construction help in Panama by A. Devar, E. Rightley, K. Erickson, and C. Erickson. D. Chalcraft provided logistic support. M. Meadors and A. Daly aided in the design of molds. L. Crothers, J. Davenport, and R. Johnson provided comments on earlier versions of this manuscript. L. Crothers also provided Fig. 1. We are very grateful to C. Aguilar, J. Córdova, K. Siu Ting, R. von May, and M. Muller Medina for their help at the Museo de Historia Natural, San Marcos, Peru. Research was funded in part by National Science Foundation (IOB-0544010), National Geographic Society (7658-04), and an East Carolina University Research and Development Grant (2006) to K.S. Research permits were obtained from the Ministry of Agriculture (INRENA) in Lima, Peru (Authorization No. 050-2006-INRENA-IFFS-DCB, No. 067-2007-INRENA-IFFS-DCB).

Toes versus Swabs? Evaluation of The Best Tissue Source for Detection of *Batrachochytrium dendrobatidis* in Field-Caught Amphibians

The pathogenic fungus *Batrachochytrium dendrobatidis (Bd;* Phylum Chytridiomycota, Class Chytridiomycetes, Order Chytridiales) has been associated with amphibian extinctions and declines throughout the planet (Berger et al. 1998; Crawford et al. 2010; Lips et al. 2006; Mendelson et al. 2006; Stuart et al. 2004). Since its discovery in 1998, researchers have documented the distribution of *Bd* (Fisher et al. 2009; Ron 2005; *Bd* maps: http://www.spatialepidemiology.net/bd-maps/), potential dispersal patterns and vectors (Johnson and Speare 2005; Lips et al. 2009), the effect of epidemics on amphibian communities (Brem and Lips 2008; Briggs et al. 2010; Lips et al. 2006; Vredenburg et al. 2010), and the life history traits and environmental factors that might contribute to pathogen virulence and/or host vulnerability (Bielby et al. 2008; Burrowes et al. 2008; Garner et al. 2009; Lips et al. 2003; Longo et al. 2010; Pounds et al. 2006). Regardless of the type of question that we are addressing, effective detection of infected individuals and estimation of *Bd* load is key to further understanding the dynamics of this disease among affected populations. At present, this is done via molecular assays using end-point PCR (Annis et al. 2004) or TaqMan quantitative real-time PCR (Boyle et al. 2004). However, the kind of tissue source (toes versus ventral skin swabs) used for detection has been rarely tested (Hyatt et al. 2007). The aim of this study is to evaluate the reliability of these sample methods applied to the same animal, in detecting *Bd* and estimating the intensity of the infection in the field at a given sampling time.

Although sampling toes are considered unethical by some authors because they may cause pain or hinder survivorship in some species (Hyatt 2007; McCarthy and Parris 2004, Phillott et al. 2007), *Eleutherodactylus coqui* is not negatively affected by toe-clipping and can regenerate a toe within 4–5 months to a round (versus the usual T-shape) disk, thus allowing for future recognition and re-sampling (Joglar 1998, Ulmar et al. 2011). In addition, the usefulness of this tissue for scientific studies such as population genetics (Burrowes and Joglar 1999), systematics (Gonsner and Collura 1996), and disease diagnostics (Longo et al. 2010; St-Amour and Lesbarrères 2007) has been recognized. In a study of population-level responses to *Bd*, toe-clips may be very valuable to assess the temporal progression of the disease and survivorship of marked individuals (Longo and Burrowes 2010). This is suitable for amphibians that can re-grow their toes quickly, but may not work well with other species. On the other hand, swabs are easily taken, non-invasive, conveniently stored, and have shown high sensitivity for *Bd* diagnosis (Hyatt et al. 2007).

Pushendorf and Bolaños (2006) compared the probability of detecting *Bd* using tissues from different body parts with histology and found that sections from the pelvic patch and the innermost finger with a fungal-specific stain (periodic acid-Shiff-PAS), were generally more effective. Hyatt et al. (2007) compared the diagnostic sensitivity of swabs, toe clips and water baths in detecting *Bd* via TaqMan qPCR assays in frogs inoculated with *Bd* in the laboratory. They define diagnostic sensitivity as the proportion of known reference animals that are *Bd* positive, that test positive for *Bd*. Their work revealed that toe clips were more effective in detecting *Bd* only at early stages of infection, and they recommend the use of swabs as the standard sampling method (Hyatt et al. 2007). Our study is different in that we evaluate the probability of detecting *Bd* in the field (unknown *Bd* status) from the same animal at a particular time using two sampling protocols. In addition, we assess the difference between swabs and toes at estimating the level of infection (*Bd* zoospore load) of individuals within a population. We expect that the results presented herein, may help scientists decide the best sampling method for *Bd* diagnostics according to the type of question they wish to address in future field studies.

TABLE 1. Number of positive *Bd* samples from *Eleutherodactylus* species obtained from swabs versus toes, and number of mismatches, positive, and negative agreements and results of corresponding McNemar's test for association between positive diagnosis of *Bd* infection on swabs versus toes sampling protocols for a given individual in the field.

Sample	No. *Bd* + in swabs	No. *Bd* + in Toes	No. Mis-matches	No. + *Bd* Agreements	No. – *Bd* Agreements	N	McNemar's Statistics
All frogs	56	61	15	19	51	85	χ^2 = 1.067, df = 1, P = 0.3017
Adults	36	41	11	33	11	55	χ^2 =1.455, df = 1, P = 0.2278
Juveniles	20	20	4	18	8	30	χ^2 = 0.250, df = 1, P = 0.6171
Locality:							
El Yunque	29	33	8	27	5	40	χ^2 = 1.125, df = 1, P = 0.2880
Carite	17	16	7	25	13	45	χ^2 = 0.000, df = 1, P = 1.00
Species:							
E. coqui	27	33	8	26	10	44	χ^2 = 3.125, df = 1, P = 0.0881
E. portoricensis	15	16	5	13	3	21	χ^2 = 0.000, df = 1, P = 1.00
E. locustus	6	4	2	4	3	10	χ^2 = 0.500, df = 1, P = 0.4795
E. richmondi	7	9	0	4	6	10	—

Methods.—Fieldwork was done in El Yunque (18.29948°N, 65.77984°W) and Carite Forest (18.090453°N, 66.03265°W) during 2009–2010. We sampled 85 individuals in four species of direct-developing frogs in the genus *Eleutherodactylus* (*E. coqui, E. portoricensis, E. locustus, and E. richmondi*), and two age classes: juveniles (N = 30) and adults (N = 55) from populations known to be infected with *Bd*. We collected tissue from individual frogs by toe clipping the distal phalange of the third toe of the foot and the second toe of the hand without special attention to right or left, and swabbing the ventral pelvic-patch region and thighs for 30 strokes for adults and 15 for juveniles. We changed gloves and flamed instruments between frogs sampled. Toes were stored in 70 % ethyl alcohol and swabs were stored dry, and frozen at –20°C. DNA for diagnosis of *Bd* infection was extracted using a Prep-Man Ultra assay (Boyle et al. 2004). *Bd* loads (number of zoospores genomic equivalents) per sample were quantified via qPCR using a Stratagene MX 3005P system and following Boyle et al. (2004).

To answer the question if detection of *Bd* was associated with the sampling method, we used McNemar's test of association for paired-data measured in the same scale (*Bd* zoopspore genomic equivalents). This test calculates the probability of association with a continuity correction and it is compared to a Chi-square table value. The null hypothesis is that an infected animal will test positive in both swabs and toe tissue. To assess if there was a significant difference between toe-clip and swab samples in measuring the intensity of *Bd* infection in a given individual, we compared zoospore loads estimated by each tissue type using a Paired T-test. For statistical analyses we used Minitab-14, and Graphpad software (http://www.graphpad.com/quickcalcs/mcnemar1.cfm).

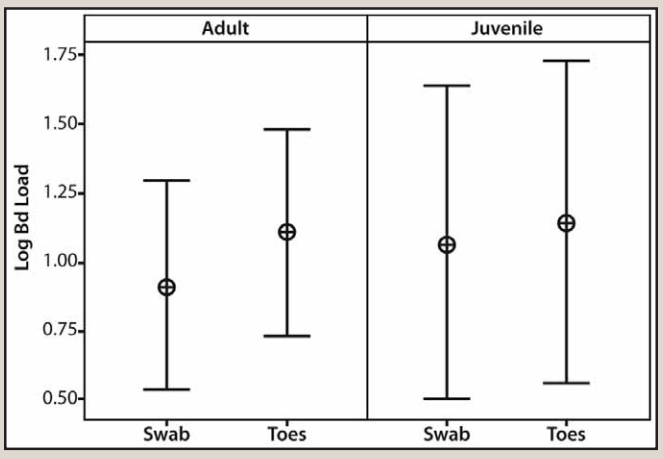

FIG. 1. Mean Log *Bd* zoospore load and 95 % confidence intervals detected by qPCR from two different tissue sources (skin swabs and toe-clips) of adults and juveniles *Eleutherodactylus* frogs.

Results.—We found no significant difference in the probability of detecting *Bd* from toe-clips or swabs. The number of mismatches in *Bd*-diagnosis between sample methods was low when compared to the times the diagnosis was in agreement (Table 1). As a result, McNemar's test for association between positive diagnosis of *Bd* and tissue source was non-significant for all samples considered in this study, as well as for every time the sample was subdivided by biologically meaningful criteria such as adults, juveniles, localities studied (El Yunque and Carite), or species (*E. coqui*, *E. portoricensis*, *E. locustus*, and *E. richmondi*; Table 1).

The *Bd* infection loads estimated by swabs versus toes, when at least one of the two tissue sources was positive, were not significantly different when all frogs were considered. When we subdivided the sample by age, we found that toes estimated a significantly greater number of zoospores than swabs in adult frogs ($\bar{x}$ swabs = 144.62 ± 47.5; $\bar{x}$ toes = 223.68 ± 74.11; T = –2.28, P = 0.013, N = 51). However, there was no difference in juveniles ($\bar{x}$ swabs = 1588.22 ± 1461.49; $\bar{x}$ toes = 672.97 ± 429.87; T = 0.87, P = 0.389, N = 29) where *Bd*-infection loads were higher than in adults and had a greater variance between samples (Fig. 1).

Discussion.—The probability of accurately detecting *Bd* on infected frogs is an important issue for studies regarding the mechanisms of *Bd* in the laboratory or prevalence of infection in the field. We show that this can be done without significant differences in the probability of detection using swabs or toes. Thus, the decision on what tissue type to use will depend on the scientist's need to mark individual frogs in species that cannot be easily distinguished by unique color marks. In amphibians that regenerate toes readily and in an identifiable manner, as *Eleutherodactylus coqui*, toes can be a useful way to distinguish individuals and follow the progression of *Bd* infection throughout a time period.

On the other hand, our results show that the estimates of infection loads are not comparable for adult *Eleutherodactylus*, where toes detect a significantly higher number of zoospores for a given individual. Hyatt et al. (2007) found higher detection

sensitivity in toe-clip samples than in swabs at early stages of infection in *Bd*-inoculated *Litoria caerulea*. The authors attribute this to low levels of hyperkeratosis and skin sloughing in recently infected hosts, which results in a lower probability of detecting the fungus using skin swabs. In Puerto Rico, we have found high prevalence and low levels of infection in adult *Eleutherodactylus*, characteristic of populations that persist in enzootic conditions (Longo et al. 2010; Longo and Burrowes 2010). Thus, the increased *Bd* infection loads obtained in toe samples from adult frogs may be due to similar physiological responses of their skin (less hyperkeratosis) at times when infection is not severe. The implication of this finding is that in enzootic conditions when *Bd* infection loads are low, the probability of false negatives may be higher when sampling with swabs versus toe clips. The fact that estimates of *Bd* load in juveniles were not significantly different between toe or swab samples is not surprising because juvenile *Eleutherodactylus* carry higher zoospore loads than adults (Longo and Burrowes 2010). In moderate to heavily infected small-sized frogs (as exemplified by juvenile direct-developers), the difference in tissue sample between tiny toes and skin swabs, may not contribute to significant differences in the estimate of infection intensity.

In summary, we have shown that *Bd* detection probability is independent of the sampling method (toe-clip versus skin swabs) in direct-developing terrestrial frogs, and that the intensity of the infection detected via qPCR in field animals may vary according to ontogenetic stage, and progression of *Bd*-infection. Since this knowledge is difficult to obtain without conducting long-term surveys, we recommend that unless necessary for marking purposes as mentioned above, scientists use swabbing as the main sampling technique, and remain consistent in the use of this source of tissue for comparisons of infection intensity between individuals in a population or a community of amphibians throughout time.

Acknowledgments.—We are grateful to N. Rivera, C. A. Rodríguez, N. Vélez, and L. Santiago for help in the field; and to P. Langhammer for suggestions on statistical analysis. Tissue samples were collected under the Puerto Rico Department of Natural and Environmental Resources permits: DRNA 2009-IC-014; DRNA 2010-IC-037. Proyecto Coquí and NSF-PRLSAMP provided funding for this work.

Comparison of Immobilization Methods for PIT Tagging Three-toed Amphiuma (*Amphiuma tridactylum*)

Amphiuma tridactylum is a large (up to 1 m and 1 kg), slimy, aquatic salamander that can deliver a powerful bite, and thus is difficult and potentially dangerous to handle (Fontenot Jr. 1999; Fontenot Jr. and Seigel 2008). Even a simple task like PIT (Passive Integrated Transponder) tag implantation is virtually impossible without restraining the animal. We have observed that forced physical restraint is undesirable because it can result in skin abrasion (from gloves or a towel), physical trauma to internal organs (e.g., liver damage), and potentially death. Recently, Brown and Forstner (2009) reported a method of handling *Amphiuma* in the field using snake restraining tubes. We found this method difficult to implement with *Amphiuma*, especially when carefully examining specimens for bites. Burgmeier et al. (2010) developed the "bender" board for restraining Eastern Hellbenders (*Cryptobranchus alleganiensis alleganiensis)*. We sought a quick method of temporarily immobilizing *A. tridactylum* individuals for examination and PIT tag implantation, comparing one method of anesthesia (isoflurane) and immersion in a cold-water bath. Alamndarz (1975) used cold water to aid transferring adult crocodilians, and Mitchell (2009) refers to cooling as a method of minimizing movement with amphibians. Mitchell (2009) discusses several anesthetics for amphibians. We selected isoflurane because preliminary trials with *A. tridactylum* individuals indicated it was safe and effective.

Methods.—Eighteen adult *A. tridactylum* were collected with baited traps (flexible fish traps; Promar 36" x 12" with ¼" mesh) baited with raw beef heart, chicken livers or most effectively, canned cat food) from a ditch and small pond in East Baton Rouge Parish, Louisiana, USA. The specimens were maintained for 1–3 days in the laboratory in aquaria at 25°C and fed one earthworm per day each.

We used isoflurane anesthesia for three of the specimens. Isoflurane anesthesia methods were those of Major et al. (2011)

Fig. 1. A Three-toed Amphiuma being weighed after cooling in ice water.

Fig. 2. A Three-toed Amphiuma after cooling in ice water. It is possible to examine the specimen leisurely, even to the point of placing them ventral side up.

and are only summarized here. We placed each individual into a body-size matched polycarbonate snake tube. We placed a cotton ball saturated with 0.2–0.5 ml (as needed) of isoflurane into head the end of the tube and plugged the ends with rubber stoppers.

Fifteen specimens were immersed in a container of water and ice for ten minutes or until they did not exhibit a righting response.

Prior to insertion, PIT tags and the syringe needle were dipped in 90% isopropyl alcohol to ensure aseptic conditions. While under anesthesia, with the individual in the clear plastic tube, the posterior third of its body was pulled from the tube, and the tail was held with a dry cloth. The PIT tag was inserted subcutaneously on the right side (dorsal view) of the body approximately 5 cm anterior to its cloaca, with the syringe provided by the manufacturer (Avid Identifications Systems, Norco, California). We inserted the syringe subcutaneously slightly farther than necessary, so as to leave ~ 1 cm of space between the PIT tag and the puncture made by the syringe, to allow subcutaneous space for fascia reformation. The insertion hole was then sealed with New Skin (solution of -Pyroxylin, Alcohol, Oil of Cloves, and 8-hydroxyquinoline).

Animals anesthetized with isoflurane were limp during and after PIT tag implantation, and the skin surface showed visibly dilated blood capillaries. When individuals were placed in water for recovery, we were concerned that they may drown, and so supported their heads above the water surface until they began moving on their own.

Because respiratory rate is reduced during anesthesia, and respiration is the primary method of voiding the isoflurane anesthetic, recovery can be facilitated by manually forcing expiration (inspiration then follows naturally by elastic recoil). Forced expiration can be induced with the investigator's thumb by pressing on the ventral side of the subject, beginning just anterior to the cloaca, and drawing the thumb in a posterior to anterior direction as far as the pectoral girdle. The lungs are basically hollow sacs that extend most of the length of the peritoneal cavity, so the sequential compression motion described above essentially squeezes the air out. This recovery facilitating method is effective, but applying it may be limited by the nature and location of the incision, etc.

Results.—For specimens subjected to isoflurane, anesthesia was achieved with less than 20 minutes of exposure, as indicated by lack of righting response and muscular tension. Recovery to the point of voluntary movement and regular breathing generally took 30–60 min, depending on the individual. However, one individual showed little or no reviving at 60 min, but was allowed to remain in shallow water, and eventually recovered after 4–6 h. Specimens subject to cold treatment retained a firm body and muscular tension. The skin surface showed visibly dilated blood capillaries, even more so than with the isoflurane treated individuals. However, the cold-treated individuals began moving on their own within one minute when placed in ambient temperature water, and showed no negative symptoms. They were able to swim and breathe as normal in 3–5 minutes, and cutaneous blood capillaries returned to normal condition within 30 minutes.

Discussion.—Both methods were effective for immobilizing *A. tridactylum*. However, the utility of each is dependent on the type of procedure being done, the amount of time required for the procedure, and the amount of time available for application of the anesthesia/immobilization procedure, recovery time, and post-procedure monitoring.

General anesthesia with isoflurane is suitable for procedures requiring a working time of 20+ minutes. This method can also work satisfactorily for short duration procedures, but it requires an extensive amount of time for application, monitoring, and recovery. Hence, its use may be impractical, particularly if a quicker temporary immobilization method is available.

The process and recovery time required for cold immobilization/narcosis may be most practical for use with a quick procedure like PIT tag implantation, which generally takes less than one minute. Applying cold to immobilize was quick and easy, as was recovery. Although it is not a replacement for chemical anesthesia when a long working procedure time is required as with general surgery, e.g., with radio transmitter implantation, we believe this method will useful to other researchers who need to perform simple procedures on difficult to handle amphibians such as *A. tridactylum*.

Acknowledgments.—The methods used in this work follow guidelines of the Society for the Study of Amphibians and Reptiles (http://www.asih.org/files/hacc-final.pdf) and were approved by the Animal Care Committee at SLU (IACUC, Protocol #0015) and LSU (protocol number 09-072).

Photographing Herpetofauna in Nature

Photographs of amphibians and reptiles taken in their environment generally lack a scale of magnification, although information on size could help identification or appreciation. The assorted reasons include the photographer's concern lest placing a scale object would scare the animal away. The solution is simple. First photograph the animal in as undisturbed a posture as possible, in its natural location. Next, put your scale object next to it. If the animal escapes, photograph the scale object in the animal's deserted position. Comparing the separate photos, with animal and with scale, based on landmarks in the substrate, enables measuring the animal on the photo or adding a scale bar.

As scale object, I carry a strip of white card or paper, on which a black ruler bar of 10 cm, with cm notches, is drawn. This is clearer than the mm notches on a real ruler, and is easier to position where needed, such as on a tree trunk (Fig. 1). However, when precise coloration is important, I use a color scale, a small ruler carrying a series of 1 cm standard Ostwald color patches (Streller and Ostwald 1939) (Fig. 2).

Sometimes it is instructive and efficient to photograph the animal on a mirror, thus including the ventral aspect (Fig. 3). One might carry a mirror in the field, to do this with animals that are to be released on the spot. However, positioning may have to take into account, that the surroundings are included in the mirror image.

Observations on the Captive Reproduction of *Colostethus pratti* (Boulenger, 1899)

Colostethus pratti (Dendrobatidae) is a diurnally active leaf litter and stream edge dwelling frog with a wide distribution in Panama and Colombia. In Panama, this species is known from the western cordilleras and western Atlantic lowlands through the central portion of the country to the eastern lowlands and cordilleras. *Colostethus pratti* is also present on Isla Colón in the Boca del Toro archipelago off of Panama's northeastern coast. In Colombia, it is known from northern portions of the central and western cordilleras in the departments of Chocó and Antioquia. This species has been recorded from 110–1160 m above sea level (Ibáñez et al. 1999; Solis et al. 2004).

Herein we report our observations on the successful captive maintenance and reproduction of *C. pratti*. Extensive information exists on the captive management for many dendrobatid frogs (e.g., Lotters et al. 2007), however there is very little information available for species of *Colostethus*. We believe the information provided herein may prove useful in future efforts to maintain *ex situ* populations of this and other species in this genus.

Specimen acquisition and husbandry methods.—1.1 *Colostethus pratti* were collected from the region of El Valle de Antón, Provincia de Coclé, Panamá and legally exported to the Atlanta Botanical Garden (ABG) in 2005 as part of the Amphibian Recovery and Conservation Coalition (ARCC) project initiated by ABG and Zoo Atlanta. The goal of the ARCC was to learn the logistics of an *ex situ* response to the rapid spread of the amphibian chytrid fungus (*Batrachochytrium dendrobatidis* [*Bd*]) through amphibian populations in Panama (Gagliardo et al. 2008).

Prior to and following importation, specimens were quarantined for a period of 30 days during which they were treated for *Bd* following a protocol suggested by Dr. Brad Lock (Zoo Atlanta, Atlanta, Georgia) and Dr. Brad Wilson (The Veterinary Clinic West, Marietta, Georgia). After quarantine and prophylactic *Bd* treatment, specimens were transferred to an enclosure measuring 60 x 30 x 90 cm furnished with live plants (*Calathea*, *Guzmania*, and *Peperomia*) for cover and to provide sites for egg deposition. The substrate consisted of a charcoal and soil mix overlaid with a layer of moistened sphagnum moss. A water source and site for tadpole deposition was provided in the form of a round glass dish measuring 10 cm in diameter and 5 cm in depth. A rock was placed in the dish at an angle to allow easy access for tadpole deposition and escape of feeder insects. Light was provided by a single 55 watt compact fluorescent fixture with a cycle of 12 hours on and 12 hours off. Temperatures ranged from 18–28°C. Humidity and moisture were maintained through use of an automated misting system. Food items were offered three times weekly and consisted largely of springtails (*Collembola* sp.) and flightless fruit flies (*Drosophila hydei* and *D. melanogaster*). Bean Weevils (*Callosobruchus maculatus*) and newly hatched Domestic Crickets (*Acheta domestica*) were offered occasionally. All food items were supplemented with alternate dustings of Repcal D3® and finely powdered Men's Health® vitamins.

In 2008, ABG acquired and outfitted an insulated shipping container, known as a "Frog Pod," for the housing of ARCC frogs, including specimens of *C. pratti* (Fenolio et al. 2009). Once transferred into this facility, the 1.1 founders were housed in a Zoo Med® terrarium measuring 30 x 30 x 45 cm (Fig. 2). Furnishings were provided as above with the addition of plastic plant pots measuring 6.35 x 6.35 x 6.35 cm placed in the enclosures on their sides to provide additional shelters and egg deposition sites. Lighting was provided in the same manner as described above. Humidity and moisture were regulated through the use of an automated misting system operating six times daily during a simulated wet season from November–April and two times daily during a simulated dry season from May–October. Individual misting events ranged from three to 10 minutes each with the shortest misting events taking place during the simulated dry season. Juveniles were housed under nearly identical conditions in groups of three or four per terrarium.

Breeding.—To date amplexus has not been observed in captive *C. pratti*, although it is assumed that this species has cephalic amplexus similar to other members of the genus in which this behavior has been observed and described (Savage 2002). Males have a loud, peeping call, appeared to establish small territories, and were observed to participate in chest-to-chest wrestling bouts.

Numerous breeding events have occurred at ABG, with the earliest taking place shortly after importation and clearance of the quarantine period in 2005. Few data exist of these early reproductions. Additional reproductive events have occurred since 2005 and the information provided herein is based on observations from 2007–2010.

Each egg mass contained 8–20 eggs laid in a single-layered cluster. These were deposited on top of leaves or within plastic hiding places at intervals of three to six weeks during the simulated wet season, with a reduction in egg deposition during the simulated dry season. Eggs were observed on the substrate and in the water dish on a few occasions. These were never viable. Both parent frogs have been observed in attendance of eggs together and independently (R. Hill, pers. obs.).

Hatching occurred 7–14 days post-oviposition. In instances where egg masses were left in the enclosure all larvae were transported to the water dish on the back of the female upon hatching (Fig. 1). In multiple instances, although an apparently adequate water source was continually available, larvae were carried for

an extended period of several days before deposition. Similarly, Wells (1980) observed females to carry larvae for up to nine days in *C. panamensis* (formerly *C. inguinalis*). On one occasion in late 2010, larvae were found in the axil of a *Guzmania* bromeliad instead of the water dish. After larvae were deposited, no further parental care was observed.

Handling of eggs and larvae.—Once discovered, eggs were typically removed from the adult enclosure on the surface on which they were deposited and placed in a covered plastic container with a small amount of water until hatching. In several cases, eggs were either left in the enclosure or not discovered until the female was seen carrying larvae. Once hatched, larvae were transferred to plastic containers measuring 25 cm x 15 cm x 10 cm that were filled to a depth of 7–8 cm with filtered tap water. Larvae were raised communally and showed no aggressive tendencies toward one another. No substrate was used and temperatures were maintained at 20–25°C. Live java moss (*Vesicularia* sp.) was included to provide cover to the tadpoles.

Larval diet consisted mainly of Sera Micron®, a commercially produced Spirulina-based finely powdered fish food, which was mixed with water to form a thick paste, and then spread onto microscope slides (Fig. 4). These were then allowed to completely dry before being offered to the larvae. Larvae were observed to rasp this dried paste off of the slides as well as incidental algal

growth on the sides of the rearing containers. Success rearing *C. pratti* larvae was also achieved using New Spectrum® sinking fish pellets and Hikari® sinking algae wafers. Food was offered daily with any remaining food from the previous day removed. Water changes of 50–60% were performed twice weekly.

Handling of metamorphs and juveniles.—Newly metamorphosed *C. pratti* measured approximately 6–8 mm SVL. Time from hatching to metamorphosis ranged from 8–13 weeks (Fig. 3). All larvae from a single clutch typically metamorphosed within a few days of each other, although on one occasion the span from the first metamorphosed individual to last from a single cohort was nearly 30 days. After all four limbs developed, newly metamorphosed *C. pratti* were moved into plastic quart-size deli cups with vented lids, roughly 1 cm of filtered water, and a small mound of moistened sphagnum moss as a haul out area. If more than one was found with all four limbs from a group of tadpoles, they were placed into the above containers together. They began feeding on springtails, newly hatched crickets, and small flightless fruitflies (*D. melanogaster*) after full absorption of the tail, which took 7–10 days. Upon absorption of the tail, additional moss was added to prevent drowning. A refuge in the form of a PVC pipe 3 cm long x 1.27 cm wide was provided (Fig. 5). Individuals were raised in this manner for several weeks to ensure easy accessibility to food items and subsequently placed into groups then moved into successively larger enclosures and as they grew in size. Growth was rapid, with some young males heard calling at six months post-metamorphosis.

Conclusions.—As the World Conservation Union (IUCN), via the Amphibian Conservation Action Plan (Gascon et al. 2007) and Amphibian Ark (www.amphibianark.org) continue to call for establishment of captive survival assurance programs for amphibian species which currently cannot be safeguarded in nature, it is crucial that husbandry protocols are developed for diverse groups of species, and that this information be shared globally (Zippel and Mendelson 2008). *Colostethus pratti* is currently listed by the IUCN Red List as a species of Least Concern, though some wild populations are in decline (Solis et al. 2004). At some sites, such as in El Copé, Provincia de Coclé, Panamá, populations have shown drastic declines in association with the arrival of the amphibian chytrid fungus (Lips et al. 2006). Of the 21 species of *Colostethus* considered by the IUCN Red List, five are listed as Near Threatened, Endangered, or Critically Endangered with an additional 12 species listed as Data Deficient (IUCN Red List, 2011). The techniques and methods used in the successful husbandry and reproduction of *C. pratti* could be useful in the development of *ex situ* management programs for other members of this genus.

Acknowledgments.–This manuscript is dedicated in memory and gratitude to Julia Beth Kaylock (1980–2009) and her passion for and dedication to amphibian conservation. Special thanks are extended to Roberto Ibáñez along with the personnel and government of the Republic of Panama. Permits were granted by the Autoridad Nacional del Ambiente (permit SEX/A-81-05). Acknowledgments also to Jennifer Cruse-Sanders and Joseph R. Mendelson, III for editorial assistance, Dante Fenolio for help with images, and Mark Mandica for husbandry assistance. Further gratitude goes to George Rabb, Cynthia Jeness, and Bill and Claire Simmons for their support of *ex situ* conservation of Panamanian amphibians.

HERPETOCULTURE NOTES

CROCODYLIA — CROCODILIANS

***CROCODYLUS NILOTICUS* (Nile Crocodile). INDUCED HATCHING.** The incubation period for *Crocodylus niloticus* eggs on commercial farms is normally 75–90 days, but occasionally exceeds 100 days (S. van As and R. Fergusson, pers. comm.). Six eggs (final trimester) from two clutches (2 + 4) laid by captive females in KwaZulu-Natal, South Africa were obtained for pox virus research underway at the Faculty of Veterinary Science, University of Pretoria. On the morning of 22 January 2010, the eggs were packed in a Coleman cooler box filled with vermiculite obtained from the same incubating room as the eggs. The eggs were isolated from each other and fully insulated by the vermiculite medium. The closed cooler was then flown in a turboprop aircraft from Richards Bay Airport to O.R. Tambo International Airport in South Africa. Precaution was taken when handling and transporting the cooler in order to prevent jarring or other disturbances. The six eggs were in the possession of J. Myburgh for the duration of transportation to and from the respective airports and for the 70-minute flight (total transport time = 210 minutes). The cooler was opened for inspection immediately prior to boarding, and all eggs were in the same condition and placement subsequent to packaging. During flight the cooler was kept wedged under the solid frame of a seat in the plane. Minor vibrations to the cooler associated with its position on the cabin floor were visibly evident during the flight.

Upon arrival at the virology laboratory, the cooler was opened and it was apparent that two of the eggs had hatched during transportation. Both hatchlings repeatedly issued the distress call typical of the species and were removed immediately. The cooler with the remaining four eggs was placed in an incubator (31°C) until the eggs could be processed after the weekend. However, one hatchling was discovered at 1000 h on 24 January and an additional two at 0730 h on 25 January. The remaining egg was sacrificed later on 25 January to salvage tissue for the planned virology study. The five hatchlings appeared healthy with intra-abdominal yolk sacs and had normal mass (mean = 75 g) and length (mean = 302 mm) values for hatchling *C. niloticus*. All hatchlings ate crickets within 24 h of emergence and exhibited normal behavior and development at time of publication.

The two eggs that hatched during transport were laid on 11 November 2009 and hatched after 72 days. The remainder of the clutch (42 eggs) that was not transported hatched 21 days later on 12 February 2010. Two eggs were infertile. Although date of deposition for the remaining four eggs could not be confirmed, most clutches from the same farm successfully hatched in the second half of February 2010.

We hypothesize that the early hatching of the *C. niloticus* eggs was induced either by vibrations the embryos were subjected to during transportation (especially in the aircraft), or by the change in barometric pressure experienced during the flight. Alternatively, hypoxic conditions in the cooler may have been responsible, but this is unlikely given the relative short transport time and the fact the cooler was opened at the airport. *Crocodylus niloticus* nests in the wild and captivity are known to hatch during low-pressure thunderstorm activity and in response to vibrations caused by the mother during nest excavation (R. Fergusson, pers. comm.). The three eggs that hatched in the two days following the flight, although still premature in regards to their respective clutch, may have come from a slightly younger clutch than the other two embryos and therefore were unable to hatch immediately due to developmental constraints.

Induced hatching caused by pathogenic (e.g., bacteria), chemical (e.g., pheromones) and physical (e.g., flooding and predator induced embryo vibrations) stimuli has been observed in a small number of vertebrates (for a review see Warkentin and Caldwell 2009. *In* Dukas and Ratcliffe [eds.], Cognitive Ecology II: The Evolutionary Ecology of Information Processing and Decision-Making, pp. 177–200. University of Chicago Press, Chicago, Illinois). Our observation suggests *C. niloticus* hatchling emergence may be significantly more plastic than previously thought. Such plasticity could allow clutches to hatch at optimum environmental timeframes, at the time chosen by the mother, or as a response to disturbance by would-be predators (triggering embryo vocalizations that signal the mother to come defend the nest). Future experiments with captive (i.e. farmed) clutches would contribute to understanding the commonality and mechanisms of induced hatching in crocodilians.

We thank K. Warkentin, S. Doody, and R. Fergusson for their infective enthusiasm and positive comments.

WARNER** (e-mail: jonathan.k.warner@gmail.com), School of Biological and Conservation Sciences, University of KwaZulu-Natal, Pietermaritzburg, South Africa.

SQUAMATA — SNAKES

***PHALOTRIS TRILINEATUS* (Littoral Blackhead). OPHIOPHAGY.** The usual diet of snakes in the tribe Elapomorphini consists of amphisbaenians (Lema et al. 1983. Comun. Mus. Ci. PUCRS 26:41–121). However, these snakes may also eat other elongate squamates. We have observed them to consume some harmless snakes (Lema et al., *op. cit.*), including an opistoglyph, which appeared to have been envenomated prior to consumption. In feeding trials we have conducted at the Laboratory of Herpetology of the Fundação Zoobotânica (FZBRS), and in those of Robert Baltar, a colleague at the Biosciences Institute of the Universidade Federal de Pelotas (UFPEL), *Phalotris lemniscatus* have consumed *Helicops infrataeniatus*, *Liophis semiaureus*, *L. pictostriatus*, and *L. sublineatus* (Lema et al., *op. cit.*). A young specimen of *Phalotris trilineatus*, captured by Roberto Baltar in Pelotas, Rio Grande do Sul, Brazil, was maintained in the Laboratóry of Herpetology of the FZBRS. It was offered a young *Oxyrhopus rhombifer*. The attack was immediate, with the *P. trilineatus* biting the *O. rhombifer* and holding on until the prey was immobilized. Subsequently, the *O. rhombifer* was swallowed in less than one minute. This observation confirms that *P. trilineatus* consumes other small snakes.

Confirmed Amphibian Chytrid in Mount Mulanje Area, Malawi

The amphibian chytrid fungus, *Batrachochytrium dendrobatidis* (*Bd*) is responsible for widespread morbidity and mortality in susceptible species, leading to population declines (Berger et al. 1998; Bosch et al. 2001; Fisher et al. 2009; Lips 1999; Rachowicz et al. 2006; Skerratt et al. 2007; Stuart et al. 2004). Although *Bd* is believed to have originated in Africa (Weldon et al. 2004), relatively little work has been done on the continent to assess its occurrence and distribution. African countries where *Bd* has been identified include Botswana, Ghana, Kenya, Lesotho, South Africa, Swaziland, Tanzania and Zambia (www.Bd-maps.net, accessed 5 November 2010; Kielgast et al. 2010). More recently sources also indicate *Bd*-positive records from Cameroon, Malawi and Uganda (Goldberg et al. 2007; Sotoz-Azat et al. 2010), Democratic Republic of Congo (Greenbaum et al. 2008), Nigeria (Imasuem et al. 2009; Imasuem et al. 2011), Gabon (Bell et al. 2011), and Morocco (El Mouden et al. 2011).

Mount Mulanje (15.9352°S, 35.6202°E; Fig. 1) is situated in southern Malawi adjacent to the border with Mozambique. The mountain rises sharply and dramatically above the surrounding Phalombe Plain (about 600 m elevation) to 3000 m elevation. It is one of the largest inselbergs (isolated mountains) in the world, and the tallest peak in south-central Africa. The Mount Mulanje area has relatively high amphibian richness with an estimated 40 species (Branch and Cunningham, unpubl. data; Channing 2001; Poynton and Broadley 1985–1991; Stevens 1974).

An amphibian survey was conducted in the Mount Mulanje area during the onset of the rainy season in November 2009 and detected 24 different amphibian species. *Bd* swabs were taken of 76 adult frog specimens (Table 1). Standard field-sampling protocols and bio-security controls were followed for collecting the samples (Brem et al. 2007). Sterile cotton-tipped swabs with sleeves were used, stored at low temperatures and sent to the National Zoological Gardens (NZG) of South Africa where *Bd* DNA was isolated following the PrepMan® Ultra protocol (Applied Biosystems™, Foster City, California). The presence and quantity of the fungus was determined using a real-time PCR TaqMan standard curve assay according to Boyle et al. (2004). The StepOnePlus™ real-time PCR system from Applied Biosystems™ was used for the TaqMan assay.

We detected *Bd* in 14 of 76 (18.42%) specimens and in 8 of 24 (33%) species (Table 1). Low sample sizes likely affected *Bd* detection probability if infection prevalence was low (Skerratt et al. 2008). We observed the highest infection load in *Amietia angolensis* and *A. johnstoni* (Table 1). The presence of *Bd* in *Amietia* has been reported in Kenya (Kielgast et al. 2010), South Africa, and Lesotho (Weldon 2005), which might indicate an increased susceptibility in this genus.

This is the first report of *Bd* infecting a species of *Arthroleptis*, a direct developer. *Arthroleptis* species are associated with decaying leaf litter on forest floors, with eggs oviposited among the leaf litter; no free-swimming tadpole exists and development is completed within the egg capsule (Channing 2001; Du Preez and Carruthers 2009). *Nothophryne broadleyi* are associated with damp moss-covered seepage over rocks (Channing 2001); this is the first time that *Bd* has been recorded in this monotypic genus.

Our records confirm the occurrence of *Bd* in amphibians in Malawi, and the Mount Mulanje area in particular. Although Sotoz-Azat et al. (2010) found one Malawian *Xenopus muelleri* tadpole infected with *Bd*, they indicated it to be an incidental finding and not a true infection. *Bd* is only associated with the keratinized skin of adult amphibians and teeth of tadpoles (Longcore et al. 1999; Berger et al. 1998). Due to the fact that *Xenopus* tadpoles are filter feeders with no teeth they are unlikely to get infected.

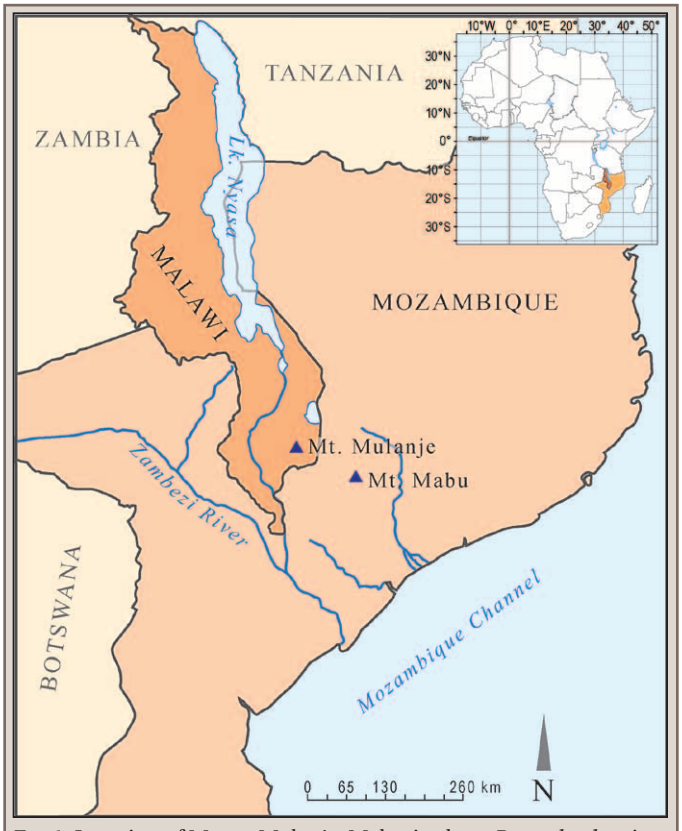

FIG. 1. Location of Mount Mulanje, Malawi, where *Batrachochytrium dendrobatidis* was detected on eight amphibian species.

TABLE 1. *Batrachochytrium dendrobatidis* infection data for amphibians of the Mount Mulanje Area, Malawi. Altitude range is divided into Low (below 700 m above sea level), Medium (700–1000 m above sea level) and High (above 1000 m above sea level). LC = least concern, ED = endangered, DD = data deficient. Endemic = known only from Mount Mulanje, Malawi.

Species	No. specimens sampled/ No. infected	CT (mean) [a]	Zoospore equivalents (ZSE) [b]	IUCN status	Altitudinal range
Afrixalus brachycnemis	4/0	0	0	LC	Low
Afrixalus crotalus	4/1	38.8	0.1	LC	Low
Amietia angolensis	16/4	20.4–33.8	1000–10	LC	High and Low
Amietia johnstoni	7/2	27.2–37.3	80–0.9	ED/Endemic	High
Amietophrynus gutturalis	1/0	0	0	LC	Low
Amietophrynus maculatus	2/0	0	0	LC	Low
Arthroleptis sp. 1	1/0	0	0	DD/Endemic	Low
Arthroleptis sp. 2	1/0	0	0	DD/Endemic	Low
Arthroleptis francei	1/0	0	0	ED/Endemic	High
Arthroleptis stenodactylus	1/0	0	0	LC	Low
Arthroleptis xenodactyloides	3/2	36.7–39.4	1–0.1	LC	Low to medium
Chiromantis xerampelina	2/0	0	0	LC	Low
Hemisus marmoratus	2/0	0	0	LC	Low
Hyperolius tuberilinguis	3/0	0	0	LC	Low
Kassina senegalensis	2/0	0	0	LC	Low
Leptopelis broadleyi	4/0	0	0	LC	Low
Leptopelis flavomaculatus	1/0	0	0	LC	Low
Leptopelis mossambicus	2/0	0	0	LC	Low
Nothophryne broadleyi	4/1	39	0.1	ED/Endemic	High
Phrynobatrachus natalensis	4/2	31.6–40.0	12–0.1	LC	Low
Ptychadena anchietae	3/0	0	0	LC	Low
Strongylopus fuelleborni	2/1	39.0	0.1	LC	High
Xenopus laevis	2/0	0	0	LC	Low
Xenopus muelleri	4/1	39.5	0.1	LC	Low
Total:	76/14				

[a] The Ct (cycle threshold) is defined as the number of cycles required for the fluorescent signal to cross the threshold. Ct levels are inversely proportional to the amount of target nucleic acid in the sample. Samples with a Ct value of more than 40 cycles and a quantity of less than 0.1 were considered negative (indicated as 0 in the table).

[b] A standard curve was constructed from the control reactions containing 100, 10, 1 and 0.1 *B. dendrobatidis* zoospores and the concentration determined for the test samples expressed as the number of Zoospore equivalents (ZSE).

Rödder et al. (2009) predicted that species with aquatic life stages occupying small geographic ranges at high altitudes were most susceptible to *Bd*-related declines; this includes the higher altitudes of East and Central Africa (see Rödder et al. 2009, figure 2A). However, in adjacent Mozambique, preliminary screening of amphibians from Mount Mabu (N = 11) provided no evidence for *Bd*-infected amphibians (Conradie, unpubl. data), although a low sample size may have precluded detection (Skerratt et al. 2008). Mount Mulanje is under pressure due to increasing socio-economic development and population growth, leading to large areas of lowland and riverine forest being cleared in the region. The illegal harvesting of endemic cedar trees, presence of invasive alien pine trees, introduction of alien fish, and uncontrolled fires are additional threat factors that may increase stress on Mount Mulanje amphibian populations, especially compared to Mount Mabu where the habitats remain fairly pristine. This may indirectly lead to an increase in *Bd* prevalence or increased susceptibility to the pathogen in the Mount Mulanje area if there are interactions among multiple stressors and *Bd*-infection rates.

Species of particular conservation concern in the Mount Mulanje area include *A. johnstoni* and *N. broadleyi* which are currently listed as Endangered according to IUCN standards. Both species are under increasing pressure due to habitat destruction, uncontrolled fires and climate change (Lovemore and Poynton 2004a, 2004b). They also have localized distributions, which make them more vulnerable to decline or extinction (Bielby et al. 2008; Cooper et al. 2008; Sodhi et al. 2008). Although originally only known to occur at high altitudes of Mount Mulanje, *N. broadleyi* subsequently has been reported to be present on isolated mountains in Mozambique: Ribaue Mountain and Mount Namuli (Poynton 1966; Timberlake et al. 2009). Additional surveys are warranted to monitor the occurrence of *Bd* on these and other endemic populations on Mount Mulanje. Such surveys can inform land and natural resource managers whether intervention may be needed to preserve the integrity of these unique amphibian communities. *Bd* is considered to be a significant factor in the decline and extinction in the wild of at least one amphibian species in Africa, the Kihansi Spray Toad, *Nectophrynoides asperginis* (Krajik 2006).

Acknowledgments.—We thank C. Bruessow (Mount Mulanje Conservation Trust, MMCT) for logistical support during the trip to Mount Mulanje, D. Nangoma (MMCT) for helping to organize permits, the Mount Mulanje Mountain Club for providing free accommodation in the huts and porters. We also want to thank D. Morgan for valuable comments on earlier drafts and two reviewers who helped improved the paper. Kathryn Ronnenberg kindly prepared the map.
